PREFACE

Thr object has been to provide a text book of practical interest and utility, fulfilling the latest requirements of the various examining bodies, and following, to a great extent, the recommendations of the Mathematical Association

Part I is intended for beginners and therefore includes a large number of examples which may be taken orally

Multiplication and Division by polynomials are deferred until after simultaneous equations of the first degree have been treated

Algebraic processes are identified with those of Arithmetic

Methods are referred to first principles, e g in the solution of equations each step is shown to be a logical application of some axiom and not a matter of arbitrary rules

A great part of the mere gymnastics of the subject, such as the reduction of complicated specimens of fractions, is made subordinate to useful and suggestive work

It has been recognised that many learners acquire some facility in manipulation of algebraic expressions without getting any power of dealing with the most important part, the solution of problems Much practice is therefore given in translating questions into a symbolical form, in order to lead the student easily to the solution of problems

A very large number of examples are introduced at every stage

Stress is laid on the importance of testing solutions and checking results, and of using approximations

Graphical work, involving largely the use of squared paper, is freely employed and interwoven throughout the book   It is

used in connection with solution of equations, square and cube roots, statistics, height and distance problems, rate problems of various kinds, indeterminate equations, logarithms, ratio and variation

Facility in finding factors and in the use of labour-saving methods is aimed at, and the Remainder Theorem is freely employed

Students are introduced at a fairly early stage to the idea of a function and to the use of functional notation

The bookwork is expressed in the manner suggested by much experience with learners as the one most readily grasped and retained

Sets of revision papers are inserted at various stages, usually at the end of what may be considered a term's work

With a view to practical utility and as a stimulus to interest, logarithms are introduced as early as possible, viz, immediately after Proportion

Thanks are due to various bodies, from whose examination papers many examples have been taken, especially to the Oxford and Cambridge Local Examination Delegates, and the Controller of His Majesty's Stationery Office

CHAPTER I.

DEFINITIONS, ETC.

वीमृसंद्रा.

1. It is assumed that the beginner is acquainted with the meanings and use of the ordinary symbols of operation, $+$, $-$, $\times$, $-$, ( ), as employed in Arithmetic The symbol / is sometimes used to denote the operation of division

Thus $10/7 = 10 - 7 = \frac{10}{7}$

2 In Arithmetic we denote quantities by *numbers*, each number having a fixed value In Algebra we denote quantities by *symbols*, generally letters, to which we may assign any value we please

Thus, in Arithmetic, 2×3 is always equal to 6, whereas $2 \times a$, or more shortly, $2a$, will have different values according to the numerical value we assign to the symbol a

When $a = 3$, $2a = 2 \times 3 = 6$ If $a = 8$, then $2a = 2 \times 8 = 16$, and so on

In Arithmetic,

$$2 \times 6 + 3 \times 6 + 5 \times 6 = (2 + 3 + 5) \times 6 = 10 \times 6 = 60$$

So in Algebra, $2a + 3a + 5a = 10 \times a$, or $10a$

In the same way, $6b - 2b = 4b$

We must also remember that since the symbols stand for numerical quantities, we may apply the ordinary Arithmetical laws in using them   Algebraic proofs of the various Arithmetical laws will be given at a later stage

As in Arithmetic $2 \times 7 = 7 \times 2$, so in Algebra $a \times b = b \times a$, or $ab = ba$

In the same way, just as 2 and 7 are the factors of the product 2×7, so a and b are the factors of the product ab, remembering that by ab we mean $a \times b$

Also $a \times b \times c = a \times c \times b = b \times a \times c$,   or $abc = acb = bac$,

just as $2 \times 7 \times 8 = 7 \times 2 \times 8 = 7 \times 8 \times 2$

Thus $3abc + 2acb + 7cab$

$$= 3abc + 2abc + 7abc$$
$$= 12abc$$

In performing the above addition we look upon abc as a single quantity

4. An Algebraic Expression   Any collection of symbols, figures, and signs involving only arithmetical operations, is called an algebraic expression

Term. The different parts of the expression connected by the signs plus (+) and minus (−) are called terms

Thus, $5x + 7y - 4z$ is an algebraic expression, and $5x$, $7y$, and $-4z$ are its *terms*

When no sign is prefixed to a term, the positive sign (+) is always understood

A *simple expression* consists of one term only, a *compound expression* of two or more terms

An expression of one term is sometimes called a **monomial**

Coefficient   In the case of a product, such as 3×7, each of the factors 3 and 7 is said to be the coefficient of the other In the same way, a is the *coefficient* of bc in the product abc, or b is the coefficient of ac, or c of ab

When one of the factors is expressed in figures, it is called the numerical coefficient of the product of the other factors

Thus in the expression $12xyz$, 12 is the numerical coefficien of xyz

Power   The power of any number or quantity is the result obtained when the number or quantity is multiplied by itself once or any other number of times

Thus aa is called the *second power* of a, aaa the *third power*, and so on

Instead of writing aa, we write it thus a^2, and call it 'a squared' In the same way we write a^3 instead of aaa, a^5 instead of $aaaaa$, and so on

Hence a^4 denotes the fourth power of a

Index   The number written above, called the index or *exponent*, indicates the number of factors

$$a \times a \times a \times a \times a \quad \text{to } n \text{ factors} = a^n$$

Square; Cube   The second power of a quantity is called its square, the third power its cube.

$$N B \text{—} a^1 \text{ is the same as } a$$

Square root   The square root of a number is that number which, multiplied by itself, gives the original number

The symbol $\sqrt{}$ is used to denote a square root

Thus
$$\sqrt{25} = 5, \text{ for } 5 \times 5 = 25$$
$$\sqrt{16a^2} = 4a, \text{ for } 4a \times 4a = 16a^2$$

Cube root   The cube root of a quantity is that quantity whose third power is equal to the original quantity

Thus, since $2^3 = 8$, 2 is the cube root of 8

The cube root of a is written thus, $\sqrt[3]{a}$

In the same way the **fourth, fifth**, etc, root of any quantity is that quantity whose *fourth, fifth*, etc, power is equal to the original quantity

The nth root of a is written thus, $\sqrt[n]{a}$.

Like and Unlike Terms   In any algebraic expression, those terms which differ only in their numerical coefficients are said to be *like* terms.

In the expression
$$6ax^2 - 7a^2x - 9abcx - 11a^2x - bcd - 3ax^2$$
$6ax^2$ and $-3ax^2$ are *like* terms, also $-7a^2x$ and $-11a^2x$, $-9abcx$ and $-bcd$ are *unlike* to one another and to all the other terms

5 Examples
$$a^2 \times a = a \times a \times a = a^3$$
$$a^n \times a^2 = a \times a \times a \times a \times a = a^5$$
$$a^4 \times a^7 = \text{eleven } a\text{'s multiplied together} = a^{11}$$

N B —a^3 is not a multiplied by itself three times, but is the product of three factors, a, a, a

$$a^2b \times b = a \times a \times b \times b = a^2b^2$$
$$a^3b^2 \times a^2b^4 = a^2 \times a^3 \times b^2 \times b^4 = a^5b^6$$
$$a^2 \times a^3x = a^5x$$
$$3ab \times 3a = 9 \times a \times a \times b = 9a^2b$$
$$12abc \times 2a^2bc = 24 \times a \times a^2 \times b \times b \times c \times c = 24a^3b^2c^2.$$

The square of $\qquad a^2 = a^2 \times a^2 = a^4$
$$a^5 = a^5 \times a^5 = a^{10}$$
$$4a^2 = 4 \times 4 \times a^2 \times a^2 = 16a^4$$

The square root of a^4 is a^2, for $a^2 \times a^2 = a^4$
$$a^6 \text{ is } a^3, \text{ for } a^3 \times a^3 = a^6$$

CHAPTER II.

NEGATIVE QUANTITIES

7 Any quantity with the sign + prefixed, or understood, is called a positive quantity, and any quantity with the sign − prefixed is called a negative quantity

Negative Quantities Arithmetically we cannot subtract 6 from 3, i e the expression $3 - 6$ has no arithmetical meaning

In Algebra however such an expression has an intelligible interpretation

This is best seen by considering a few examples

If a farmer buys 7 cows, and sells 4 cows, he has 3 *more* than he had at the start On the other hand, if he buys 4 cows, and sells 7, he has 3 *less* than at first

We express this algebraically thus,

$$7 \text{ cows} - 4 \text{ cows} = +3 \text{ cows}$$
$$4 \text{ cows} - 7 \text{ cows} = -3 \text{ cows}$$

Again, if a man gains £10 and loses £6, he has £10 – £6, i e. £4, *more* than at first If, on the other hand, he gains £6 and loses £10, he has £4 *less* than at first,

i e $$£10 - £6 = +£4,$$

and $$£6 - £10 = -£4$$

Moreover, if he loses £10 and then gains £6, he will then have £4 *less* than at first,

i e $$-£10 + £6 = -£4$$

If a man runs 120 yds along a road, and then runs 90 yds towards his starting point, he will be 30 yds from his starting place But if he first runs 90 yds and then 120 yds backwards, he will still be 30 yds from his starting place, but *on the opposite side of it*

$$120 - 90 = 30, \qquad 90 - 120 = -30$$

Thus we see that $+4$ and -4 are the exact *opposite* of one another If we consider a man's income, $+£4$ will represent an *increase*, whilst $-£4$ will represent an equal *decrease* $+4$ yds and -4 yds represent 4 yds *in opposite directions*, and so on

Suppose a man loses first £10 and then again loses £4, he is £14 poorer than at first

That is, $$-£10 - £4 = -£14$$

Thus $-3 - 2 = -5$, and $-5 - 6 = -11$

Now instead of using £, or cows, or yards, let us use a symbol

We then have,
$$10a - 6a = +4a$$
$$6a - 10a = -4a$$
$$- 6a - 10a = -16a$$
$$-10a - 6a = -16a$$
$$-10a + 6a = -4a$$

8 Graphical Illustrations   Take a str line XOX′ of unlimited length, and let all distances measured *to the right* be considered positive, whilst all distances measured in the opposite direction, from right to left, are taken as negative
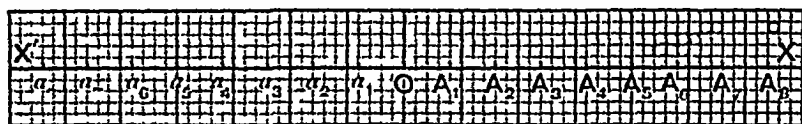

Take $OA_1 = A_1A_2 = A_2A_1 = \quad = b$ along OX,

and $Oa_1 = a_1a_2 = a_2a_3 = \quad = b$ along OX′,

Taking O as the starting point in each case,

     OA_6 denotes $+6b$, whilst Oa_6 denotes $-6b$, and so on

Also A_3A_7 denotes $+4b$, whilst A_7A_3 denotes $-4b$

Thus $6b$ is denoted by OA_6 (6 spaces *to the right*), and A_6A_4 denotes $-2b$ (2 spaces *to the left*),

$$6b - 2b = OA_4 = 4b$$

Again, still starting from O, $-2b$ is denoted by Oa_2 (2 spaces *to the left*) and $+5b$ by a_2A_3 (5 spaces *to the right*)

$$-2b + 5b = OA_3 = 3b$$

Again, $-3b$ is denoted by Oa_3, and $-4b$ by a_3a_7, both distances being measured *to the left*,

$$-3b - 4b = Oa_7 = -7b$$

‘ Once more,

    $-7b$ is denoted by Oa_7 (7 spaces in the negative direction)

    $+4b$ a_7a_3 (4   positive   ),

        $-7b + 4b$ is denoted by Oa_3

$$-7b + 4b = -3b$$

Graphical Examples

Use graphical illustrations to prove the following (squared paper will be found useful)

42 $4-3=1$	43 $7-4=3$	44 $6-2=4$
45 $-8+5=-3$	46 $2-5=-3$	47 $-7+2=-5$
48 $-2-3=-5$	49 $-4-5=-9$	50 $5x-3x=2x$
51 $-3x+8x=5x$	52 $-2x-4x=-6x$	53 $-5x+x=-4x$
54. $-2x-3x=-5x$	55 $-7x+4x=-3x$	

9 The order in which additions and subtractions are performed is immaterial   If you take 4 from 6 and then add 3 the result is the same as if you first add the 3 to the 6 and then subtract the 4   The same principle holds good with regard to algebraical expression, thus $6a-4b+3c$ is equal to $6a+3c-4b$

This is generally accepted as axiomatic, but may with advantage be illustrated graphically
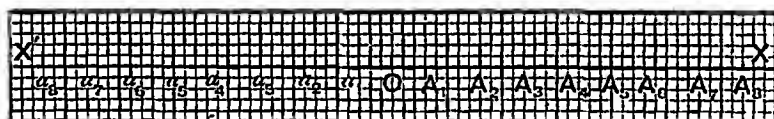

With the above diagram, using the same hypotheses with regard to signs, etc , as in Art 8,

$4b+3b-5b$ takes us from O to A_4 (4 spaces), then from A_4 to A_7 (3 spaces), then from A_7 to A_2 (5 spaces in the negative direction),

$$4b+3b-5b=OA_2=2b$$

In the same way $4b - 5b + 3b$ takes us first from O to A_4, then from A_4 to a_1 (5 spaces in the negative direction) then from a_1 to A_2 (3 spaces in a positive direction), $i\,e$ to the same point as in the first case,

$$4b + 3b - 5b \text{ is the same as } 4b - 5b + 3b$$

Again, $6b - 4b - 3b$ takes us first from O to A_6 (6 spaces), then from A_6 to A_2 (4 spaces in the negative direction), then from A_2 to a_1 (3 spaces in the negative direction),

$$6b - 4b - 3b = Oa_1 = -b$$

In the same way $-4b - 3b + 6b$ takes us first from O to a_4 (4 spaces in the negative direction), then from a_4 to a_7 (3 spaces in the negative direction) and then from a_7 to a_1 (6 spaces in the positive direction),

$$-4b - 3b + 6b = Oa_1 = -b,$$

$$6b - 4b - 3b = -4b - 3b + 6b$$

11 An algebraic expression consisting entirely of unlike terms cannot be simplified unless the values of the symbols are given

If a man has 7 pigs, 3 cows, and 3 geese, he does not know the value of 7 pigs + 3 cows + 5 geese, unless he knows the value of a pig, the value of a cow, and the value of a goose

In the same way we cannot simplify the expression $7a + 3b + 5c$, unless we are given the values of a, b, and c

On the other hand, if an algebraical expression consists entirely of like terms, we can collect these terms into one

Just as   2 cows + 3 cows + 5 cows = 10 cows,

so $2a + 3a + 5a = 10a$

                 7 pigs − 3 pigs = 4 pigs

In the same way $7a - 3a = 4a$

       11 geese − 4 geese = 7 geese,

             $11x - 4x = 7x$

    12 horses − 7 horses + 2 horses = 7 horses

In the same way $12y - 7y + 2y = 7y$

12   In Arithmetic we know that

$$2(3 + 4) = 2 \times 3 + 2 \times 4 = 6 + 8 = 14$$

Or otherwise, $2(3 + 4) = 2 \times 7 = 14$

In Algebra $2(3a + 4a) = 2 \times 3a + 2 \times 4a = 6a + 8a = 14a$

Or otherwise, $2(3a + 4a) = 2 \times 7a = 14a$

Let us now consider the expression $2(3a + 4b)$, noticing that the terms $3a$ and $4b$ are *unlike*

$2(3a + 4b) = 2 \times 3a + 2 \times 4b = 6a + 8b$, and this expression cannot be further simplified unless the values of a and b are given, for the terms $6a$ and $8b$ are unlike

Thus we see that the second method used in the above arithmetical examples cannot be used in Algebra when the terms are unlike

13 **Example 1** Express $4a+2b-3c-2a+b-c$ in its simplest form

$$4a+2b-3c-2a+b-c$$
$$=4a-2a+2b+b-3c-c$$

$$=2a+3b-4c$$

CHAPTER III

SIMPLE BRACKETS

14 In Arithmetic when a number of terms are included within brackets ( ) it is understood that the terms within the brackets should be considered *as a whole*

Thus $8+(7+5)$ means that we first add 7 and 5, and then add the result to 8

When a group of terms within brackets has the positive sign (+) prefixed, the brackets may be removed without changing any of the signs within the brackets

I To prove that $a+(b+c)=a+b+c$

P ———a——— Q —b— R —c— S
Let the straight lines PQ, QR, RS represent a, b, c respectively

Then $\qquad a+(b+c)=PQ+(QR+RS)=PQ+QS$
$$=PQ+QR+RS=a+b+c$$

II *To prove that $a+(b-c)=a+b-c$*

P ——————— Q ——— S ——————— R (Fig 1)

P ——————— S ——— Q ——————— R (Fig 2)
Representing a, b, c by straight lines as before, remembering that we must draw RS in the opposite direction to PQ and QR, (see Art 9) $a+(b-c)=PQ+(QR-SR)$
$$=PQ+QS \text{ in fig (1) and } PQ-SQ \text{ in fig (2)}$$
$$=PS \text{ in each case}$$
$$=PQ+Q\dot{R}-SR \text{ in each case}$$
$$=a+b-c$$

Also, since we may write algebraic terms in any order,
$$-c+b=b-c,$$
$$a+(-c+b)=a+(b-c)=a+b-c=a-c+b$$

We have thus proved the rule

When a group of terms within brackets has the negative sign ($-$) prefixed, the brackets may be removed on changing the signs of all the terms within the brackets

P ——————— S ——— R ——————— Q
As above $a-(b+c)=PQ-(RQ+SR)=PQ-SQ=PS$
$$=PQ-RQ-SR=a-b-c$$

P ——————— R ——— S ——————— Q
Also $\qquad a-(b-c)=PQ-(RQ-RS)=PQ-SQ=PS$
$$=PQ-RQ+RS=a-b+c$$

Again, since terms may be written in any order,
$$a-(-c+b)=a-(b-c)=a-b+c=a+c-b$$

The rule is therefore established

15. In addition to the ordinary brackets, we sometimes use a line, called a "vinculum," drawn over the terms to be connected

Thus $a - \overline{2b + 3c}$ is the same as $a - (2b + 3c)$

In Arithmetic we know that $\dfrac{3 + 5}{2}$ is the same as $\dfrac{3}{2} + \dfrac{5}{2}$

So in Algebra $\dfrac{3x + 4a}{5}$ is the same as $\dfrac{3x}{5} + \dfrac{4a}{5}$

Here the "vinculum" _____, drawn underneath, has the same value as a pair of brackets

For instance $3 + \dfrac{2x - 4}{3} = 3 + \tfrac{1}{3}(2x - 4) = 3 + \dfrac{2x}{3} - \dfrac{4}{3}$

Also $3 - \dfrac{2x - 4}{3} = 3 - \tfrac{1}{3}(2x - 4) = 3 - \dfrac{2x}{3} + \dfrac{4}{3}$

As in Arithmetic $3(2 + 5) = 3 \times 2 + 3 \times 5$,
so in Algebra $4(a + b) = 4a + 4b$

16. **Example 1** Prove, by removing the brackets, that
$$7 - (x + 2) + (3 - 2x) - (-6x + 3) = 5 + 3x$$
The given expression $= 7 - x - 2 + 3 - 2x + 6x - 3$
$$= 7 + 3 - 2 - 3 + 6x - x - 2x$$
$$= 10 - 5 + 6x - 3x$$
$$= 5 + 3x \qquad\qquad \text{Q E D}$$

Example 2 Prove that $4a - 2(a + b) + 3(a - b) = 5a - 5b$
$$4a - 2(a + b) + 3(a - b) = 4a - 2a - 2b + 3a - 3b$$
$$= 4a + 3a - 2a - 2b - 3b$$
$$= 7a - 2a - 5b$$
$$= 5a - 5b \qquad\qquad \text{Q E D}$$

Example 3 Simplify the expression
$$\frac{5x - 15}{5} - \frac{12 - 42x}{6} + \frac{27x - 54}{9}$$
The given expression $= \dfrac{5x}{5} - \dfrac{15}{5} - \dfrac{12}{6} + \dfrac{42x}{6} + \dfrac{27x}{9} - \dfrac{54}{9}$
$$= x - 3 - 2 + 7x + 3x - 6$$
$$= 11x - 11$$

45 $\dfrac{8-9x}{3}-\dfrac{7-21x}{7}+\dfrac{20+25x}{5}=5x+5\tfrac{2}{3}$

ADDITION

17 In Arithmetic the sum of 2 and 3 may be written $2+3$
So in Algebra the sum of a and b is $a+b$

Using the rules for removing brackets, the sum of a and $-b$ is
$$a+(-b)=a-b$$
When like terms are to be added together, they may (Art 9) be collected into one term

Unlike terms cannot thus be collected

The sum of $2a$, $-3a$, and $5a$ is
$$2a+(-3a)+5a=2a-3a+5a=4a$$

The sum of x^2, $-3x$, and -6 is $x^2+(-3x)+(-6)$ which is equal to x^2-3x-6, and this cannot be shortened, since the terms are all unlike

When a number of like terms are collected into one term, the result is called their algebraic sum, even though some of the terms may be connected by the negative or minus sign

18 Example 1   Add together $\dfrac{5x}{6}$ and $\dfrac{x}{5}$

$$\text{The sum required} = \frac{5x}{6} + \frac{x}{5}$$

$$= \frac{5 \times 5x}{5 \times 6} + \frac{6x}{5 \times 6}, \text{ (as in Arithmetic)}$$

$$= \frac{25x + 6x}{30} = \frac{31x}{30}$$

Example 2   Find the sum of $\dfrac{x^2}{3}$ and $-\dfrac{2x^2}{7}$

$$\text{The sum required} = \frac{x^2}{3} - \frac{2x^2}{7}$$

$$= \frac{7x^2}{7 \times 3} - \frac{3 \times 2x^2}{7 \times 3}$$

$$= \frac{7x^2 - 6x^2}{21} = \frac{x^2}{21}$$

23 Example 1. Subtract $3a - 2b - 2c$ from $5a - 3b - 4c.$

$\qquad$ The reqd. result $= 5a - 3b - 4c - (3a - 2b - 2c)$
$$\qquad\qquad = 5a - 3b - 4c - 3a - 2b - 2c \qquad\qquad (1)$$
$$\qquad\qquad = 5a - 3a - 3b - 2b - 4c - 2c \qquad\qquad (2)$$

Example 2. Subtract $3x - 2x^2 - 6$ from $7x - 5 - 2x^3 - 4x^2$

In cases such as this it is generally best to arrange the expressions in order of descending powers of x.

Arranging the expressions in *descending* powers of x,

the reqd result $= 4x^3 - 2x^2 + 7x - 5 - (-2x^2 + 3x - 6)$

$$= 4x^3 - 2x^2 + 7x - 5 + 2x^2 - 3x + 6 \qquad (1)$$

$$= 4x^3 - 2x^2 + 2x^2 + 7x - 3x - 5 + 6 \qquad (2)$$

$$= 4x^3 + 4x + 1$$

When the student has had a little practice, he will be able to shorten the work by omitting lines marked (1) and (2) in the above

24. The work of subtraction is often conveniently arranged as follows

Subtract $5a - 3b + 4c$ *from* $6a - 5b - 3c$

$$\begin{array}{r} 6a - 5b - 3c \\ 5a - 3b + 4c \\ \hline a - 2b - 7c \end{array}$$

Explanation. We see from the examples previously worked out, that we must change the signs of all terms in the expression to be subtracted and then take the algebraic sum of the two lines

$$6a - 5a = a, \qquad -5b + 3b = -2b, \qquad -3c - 4c = -7c$$

The signs need not be actually changed ; the change may be made *mentally*

Subtract $3a^4 - 4a^3 + 2a^2 + 5a$ *from* $2a^5 + 3a^4 - 5a + 4$

$$\begin{array}{r} 2a^5 + 3a^4 \qquad\qquad - 5a + 4 \\ 3a^4 - 4a^3 + 2a^2 + 5a \\ \hline 2a^5 \qquad + 4a^3 - 2a^2 - 10a + 4 \end{array}$$

Explanation $2a^5 - 0 = 2a^5$, $3a^4 - 3a^4 = 0$, $0 + 4a^3 = 4a^3$,

$$0 - 2a^2 = -2a^2, \qquad -5a - 5a = -10a, \qquad 4 - 0 = 4$$

CHAPTER IV

MULTIPLICATION

Rule of Signs

25 We know that

$$+2\times+3=+6, \quad \text{also} \quad +a\times+b \text{ is represented by } +ab \quad (1)$$

Again, $-3\times+2$ means -3 taken twice

i e $-3\times+2=-3+(-3)=-3-3=-6$

We therefore deduce that $-a\times+b=-ab$ (2)

Next let us consider $+3\times-2$

This means $+3$ taken -2 times, and therefore has no arithmetical meaning

It bears however an algebraic interpretation

Remembering the convention of signs for direction (Art 8), we see that $+3$ taken -2 times is the same as $+3$ taken $+2$ times, *but in the opposite direction*

$$+3 \times -2 = +3 \times +2 \text{ with the opposite sign,}$$
$$= +6 \text{ with the opposite sign,}$$
$$= -6$$

Algebraically therefore,

$$+a \times -b = -ab \qquad (3)$$

Lastly let us consider the product -3×-2

This denotes -3 taken -2 times

remembering the convention of sign for direction, this is the same as -3 taken twice, *but in the opposite direction,*

$$= -6 \text{ in the opposite direction,}$$
$$= +6$$

in algebra we say that $-a \times -b = +ab \qquad (4)$

Examining the results (1), (2), (3), (4), we have the following rule of signs

Terms with like signs multiplied together give plus $(+)$

Terms with unlike signs multiplied together give minus $(-)$

Indices

26　By definition, $a^3 = a \times a \times a$,

and $a^4 = a \times a \times a \times a$

$$a^3 \times a^4 = a \times a \times a \times a \times a \times a \times a \qquad \text{(7 factors)}$$
$$= a^7 \text{ by definition}$$

In the same way $a^2 \times a^3 = a \times a \times a \times a \times a$
$$= a^5$$

In each case the index of the product is the sum of the indices of the factors

We therefore deduce the following law

To multiply two powers of the same quantity, add the indices of the factors

The continued product of a number of quantities is the result when they are all multiplied together

Thus the continued product of 2, 3, 4 is $2 \times 3 \times 4 = 24$

$$a, b, c, \text{ is } abc$$

$$a^2, a^3, a^4 \text{ is } a^9$$

$$-a, 2a, -3a \text{ is } 6a^3$$

$$-a, -2a, -3a \text{ is } -6a^3$$

(3) $-4x^2y \times -5x^3y = +4 \times 5 \times x^2 \times x^3 \times y \times y$ (Like signs give plus)

28 *To find the product of* $(x+3)$ *and* $(x+4)$

First let us regard $(x+3)$ as a single quantity, a suppose

$$(x+3) \times (x+4) = a \times (x+4)$$
$$= ax + 4a$$
$$= (x+3) \times x + 4\,(x+3)$$
$$= x^2 + 3x + 4x + 12$$
$$= x^2 + 7x + 12$$

Examining the above, we see that it is the same as multiplying $(x+3)$ by x and by 4 and adding the results

To find the product of $(x-2)$ *and* $(x-5)$

Regarding $(x-2)$ as a single quantity, a suppose,

$$(x-2) \times (x-5) = a \times (x-5)$$
$$= ax - 5a$$
$$= x(x-2) - 5\,(x-2)$$
$$= x^2 - 2x - 5x + 10$$
$$= x^2 - 7x + 10$$

Again, we see that this is the same as multiplying $(x-2)$ by x and by -5, and then taking their algebraic sum

The work may conveniently be arranged thus

$$
\begin{array}{l}
x - 2 \\
x - 5 \\
\hline
x^2 - 2x \qquad \text{(multiplying } x-2 \text{ by } x) \\
\quad -5x + 10 \qquad \text{(multiplying } x-2 \text{ by } -5, \text{ and placing like}\\
\hline
x^2 - 7x + 10 \qquad \text{(adding)} \qquad \text{terms underneath one another)}
\end{array}
$$

N B —$(x+3) \times (x-2)$ is usually written thus, $(x+3)(x-2)$

29. Example 1   Multiply $x+a$ by $x+b$

$$
\begin{array}{l}
x + a \\
x + b \\
\hline
x^2 + ax \\
\qquad\quad bx + ab \\
\hline
x^2 + ax + bx + ab
\end{array}
$$

This may be written $x^2 + (a+b)x + ab$

This result is true whatever values we give to a and b, positive or negative

Hence
$$(x+2)(x+5) = x^2 + (5+2)x + 5 \times 2 = x^2 + 7x + 10$$
$$(x-3)(x-5) = x^2 + (-3-5)x + (-5)(-3) = x^2 - 8x + 15$$
$$(x-3)(x+7) = x^2 + (-3+7)x + (-3)(7) = x^2 + 4x - 21$$
$$(x+3)(x-9) = x^2 + (3-9)x + (3)(-9) = x^2 - 6x - 27$$

After a little practice the student will be able to write down such products at sight

Example 2   Multiply $5+3x$ by $7-2x$

$$
\begin{array}{r}
5+3x \\
7-2x \\
\hline
35+21x \\
-10x-6x^2 \\
\hline
35+11x-6x^2
\end{array}
$$

Example 3   Multiply $ay+b$ by $cy-d$

$$
\begin{array}{r}
ay+b \\
cy-d \\
\hline
acy^2+bcy \\
-ady-bd \\
\hline
acy^2+bcy-ady-bd
\end{array}
$$

Example 4.   Multiply $a+b$ by $a-b$

$$
\begin{array}{r}
a+b \\
a-b \\
\hline
a^2+ab \\
-ab-b^2 \\
\hline
a^2-b^2
\end{array}
$$

$$\text{i e}\quad (a+b)(a-b)=a^2-b^2$$

This result is very important   It is true for all values of a and b

Hence
$$(a+2)(a-2)=a^2-2^2=a^2-4$$
$$(a+1)(a-1)=a^2-1$$
$$(x+a)(x-a)=x^2-a^2$$
$$(2x+3a)(2x-3a)=(2x)^2-(3a)^2$$
$$=4x^2-9a^2$$

SQUARES

30          $(x+a)^2 = (x+a)(x+a) = x^2+ax+ax+a^2$
$$= x^2+2ax+a^2$$

This is true for all values of a

Hence $(x+2)^2 = x^2+4x+4$
$$(x+7)^2 = x^2+14x+49$$

$(x-a)^2 = (x-a)(x-a) = x^2-ax-ax+a^2$
$$= x^2-2ax+a^2$$

This is also true for all values of a

Hence $(x-3)^2 = x^2-6x+9$
$$(x-8)^2 = x^2-16x+64$$

From the above we gather that

The square of the sum of two quantities is equal to the sum of their squares plus twice their product

The square of the difference of two quantities is equal to the sum of their squares minus twice their product

32 The formulae

$$(a+b)^2=a^2+2ab+b^2 \quad \text{and} \quad (a-b)^2=a^2-2ab+b^2$$

may be used with great advantage in arithmetical work

$$99^2=(100-1)^2=10,000-200+1=9,801$$

$$101^2=(100+1)^2=10,000+200+1=10,201$$

$$105^2=(100+5)^2=10,000+1000+25=11,025$$

$$100\ 5^2=(100+5)^2=10,000+100+25=10,100\ 25$$

These formulae may often be used in approximations

$$(100\ 03)^2 = (100 + 03)^2$$
$$= 10,000 + 200 \times 03 + \cdot 0009$$
$$= 10,000 + 6 + 0009$$
$$= 10,006\ 00 \text{ correct to two dec places}$$

In giving approximate values, 5 or more counts as unity Thus 79 7, 79 5, 79 8 would count as 80, correct in whole numbers

On the other hand, 79 3, 79 2 would be taken as 79

In the same way, 6 035729 would be taken as

$$6\ 04 \qquad \text{correct to two decimal places}$$
$$6\ 036 \qquad\qquad\quad \text{three}$$
$$6\ 0357 \qquad\qquad\quad \text{four}$$
$$6\ 03573 \qquad\qquad\quad \text{five}$$

Using the formula $(a+b)(a-b) = a^2 - b^2$

$$99 \times 101 = (100 - 1)(100 + 1)$$
$$= 10,000 - 1 = 9999$$

Also $99\ 6 \times 100\ 4 = (100 - 4)(100 + 4)$
$$= 10,000 - 16$$
$$= 9999\ 84$$

$$15\ 6 \times 14\ 4 = (15 + 6)(15 - 6)$$
$$= 225 - 36$$
$$= 224\ 64$$

Examining the results in (1), (2), (3), (4), we have the following rule of signs for division

Terms with like signs divided by one another give plus ($+$)

Terms with unlike signs divided by one another give minus ($-$)

$N B$—The rule of signs in division is the same as that in multiplication

35          $a^5 = a \times a \times a \times a \times a,$ by definition,

and $a^3 = a \times a \times a,$

$$a^5 - a^3 = \frac{a \times a \times a \times a \times a}{a \times a \times a} = a \times a$$
$$= a^2$$

In the same way, $a^7 - a^3 = \frac{a \times a \times a \times a \times a \times a \times a}{a \times a \times a}$
$$= a^4$$

In each case the index of the *quotient* is the index of the dividend *diminished by* the index of the divisor

We therefore deduce the following law

To divide one power of a quantity by another power of the same quantity, subtract the index of the divisor from the index of the dividend.

36   Examples

(1) $5x^2 \div 5 = \frac{5 \times x^2}{5} = x^2$

(2) $5x^7 - -5x^2 = -\frac{5x^7}{5x^2}$ (Unlike signs give minus)
$$= -x^5 \qquad (7-2=5)$$

(3)
$$-35a^3b^2c \div -7abc$$
$$= +\frac{35a^3b^2c}{7abc} \quad \text{(Like signs give plus)}$$
$$= 5a^2b$$

(4)
$$(6a - 9b + 3c) \div - 3$$
$$= -\frac{6a}{3} + \frac{9b}{3} - \frac{3c}{3}$$
$$= -2a + 3b - c$$

(5)
$$(28a^7b^4 - 20a^5b^3 - 36a^4b^5) \div 4a^2b^2$$
$$= \frac{28a^7b^4}{4a^2b^2} - \frac{20a^5b^3}{4a \cdot b^2} - \frac{36a^4b^5}{4a^2b^2}$$
$$= 7a^5b^2 - 5a^3b - 9a^2b^3$$

(6)
$$\frac{4x^2y - 14xy^2 - 22xy}{2xy} = \frac{4x^2y}{2xy} - \frac{14xy^2}{2xy} - \frac{22xy}{2xy}$$
$$= 2x - 7y - 11$$

After a little practice, the student will be able to write the answer down at once in examples like the above

34   $27x^4y^3z^6 - 45x^5y^4z^5 + 54x^6y^7z^4$ by $9x^3y^2z^2$

Following the law of indices, what is the quotient when

35   a^m is divided by a^n 36 a^n is divided by a^3

37   x^4 x^p 38 $6x^n$ $-2x^4$

39      $27x^ny^n$ $3x^ny^m$ 40 $-54x^3y^3$ $-6x^ny^n$

37   We have already seen that $x(x + 2) = x^2 + 2x$

The converse therefore is true, viz

$$x^2 + 2x = x(x + 2)$$

Hence $(x^2 + 2x) \div (x + 2) = \dfrac{x(x + 2)}{x + 2} = x$

Divide $x^2 + 5x + 6$ by $x + 2$

$$(x^2 + 5x + 6) \div (x + 2) = \frac{x^2 + 5x + 6}{x + 2}$$

$$= \frac{x^2 + 2x + 3x + 6}{x + 2}$$

$$= \frac{x^2 + 2x}{x + 2} + \frac{3x + 6}{x + 2} \quad \left(\text{Just as } \frac{3 + 9}{5} = \frac{3}{5} + \frac{9}{5} \text{ in Arithmetic}\right)$$

$$= \frac{x(x + 2)}{x + 2} + \frac{3x + 6}{x + 2}$$

$$= x + \frac{3x + 6}{x + 2}$$

$$= x + \frac{3(x + 2)}{x + 2}$$

$$= x + 3$$

The above is worked out in full detail and should be studied carefully

The work however is more conveniently arranged as follows

$$x+2 \;)\; x^2+5x+6 \;(\; x+3$$
$$\underline{x^2+2x}$$
$$+3x+6$$
$$\underline{+3x+6}$$

If the two methods are compared, it will be seen that they differ only in arrangement

It should be observed that the second method is analogous to that used in Arithmetic

38 **Example 1** Divide $15x^2-26x+8$ by $5x-2$

$$5x-2 \;)\; 15x^2-26x+8 \;(\; 3x-4$$
$$\underline{15x^2-\;\; 6x} \hspace{3cm} (1)$$
$$-20x+8 \hspace{3cm} (2)$$
$$\underline{-20x+8} \hspace{3cm} (3)$$

$15x^2-5x=3x$, $3x$ is the first term of the quotient

$3x(5x-2)=15x^2-6x$, and we thus obtain line (1)

Line (2) is obtained by subtraction, and by bringing down the term $+8$

$-20x-5x=-4$, -4 is the second term of the quotient

$-4(5x-2)=-20x+8$, and we thus obtain line (3)

There is no remainder

Example 2 Divide x^2-16 by $x+4$

$$x+4 \;)\; x^2-16 \;(\; x-4$$
$$\underline{x^2+4x}$$
$$-4x-16$$
$$\underline{-4x-16}$$

Example 3 Divide $6-13a+6a^2$ by $2-3a$

$$2-3a \;)\; 6-13a+6a^2 \;(\; 3-2a$$
$$\underline{6-\;\; 9a}$$
$$-\;\; 4a+6a^2$$
$$\underline{-\;\; 4a+6a^2}$$

CHAPTER VII.

SIMPLE EQUATIONS WITH ONE UNKNOWN QUANTITY

40 When we express algebraically the fact that two expressions are equal, that statement is called an **equation.**

Thus $2a - 3b = -3b - 2a$ is an equation

Moreover, the above equation is true for all values of a and b, the symbols used.

On the other hand, the equation $x - 3 = 5$, is evidently only true when x is equal to 2, $x - 3 = 0$ is true only when x is equal to 3

An equation which is only true when the symbols have certain particular values is called a **conditional equation,** or an **equation of condition.**

An equation which is true for all values of the symbols used is called an **identity**

Simple Equations of Condition

The two parts of an equation on either side of the sign of equality are called its **sides** or **members**

We see that the equation $x - 4 = 0$ is true when $x = 4$

The value 4 is said to **satisfy** the equation

The process of finding that value of x which will satisfy an equation is called **solving** the equation.

An equation which, when simplified, involves one symbol in the first degree only is called a **simple equation** with regard to that symbol, and the symbol used is called the **unknown quantity**

The value of the unknown quantity which satisfies an equation is called a **root** of the equation, a **solution** of the equation.

41 It will be seen later, that the solution of equations is a most important branch of Mathematics

In the case of Simple Equations with one unknown quantity the process consists mainly in the use of four axioms

(1) If equals be added to equals the sums are equal
    Thus if $x = a$, $x + 2 = a + 2$

(2) If equals be taken from equals the remainders are equal
        If $x = b$, $x - 5 = b - 5$

(3) If equals be multiplied by equals the products are equal
        If $x = a$, $3x = 3a$

(4) If equals be divided by equals the quotients are equal
        If $5x = 10$, $x = 2$

Examples   VII a

1 $2x = 6$	2 $3x = 9$	3 $5x = 20$	4. $4x = -20$
5 $17x = 51$	6 $11x = -33$	7 $-x = 6$	8 $7x = 0$

29 $-5x + 7x = 7 - 5$ 30 $x + 2x - 6x = 0$ 31 $9x - 3x = -36 + 30$

32 $-11x + 7x = -8 + 12$ 33 $x - 5x - 4x = -16$

34 $7x - 2x - x = 19 - 3$ 35 $-3x - 4x - 7x = -48 + 20$

36 $15x - 3x + x = 37 - 11$ 37 $7x + x - 5x = 21 - 16 + 4$

38 $-x - 2x - 3x = -7 - 4 - 10$ 39.) $11x - 5x + 6x = -35 + 11$

40 $5x = 1$	41 $2x = 4$	42 $7x = 21$	$\overline{43.}$ $3x = 9.$
44. $5x = 05$	45 $7x = 21.$	46. $-8x = 24.$	

42   **Example 1**   Solve the equation $3x+2=22-7x$

$$3x+2=22-7x$$

Adding $7x$ to both sides, $3x+7x+2=22-7x+7x$, $(Ax\ 1)$

         i e. $10x+2=22$

Taking 2 from each side, $10x+2-2=22-2$, $(Ax\ 2)$

         i e $10x=20$

Dividing both sides by 10, $x=2$, $(Ax\ 4)$

       2 is the reqd root of the equation

To verify the fact that 2 is a root of the equation $3x+2=22-7x$

When $x=2$, $3x+2=3\times2+2=8$

      $22-7x=22-7\times2=22-14=8$

      $3x+2=22-7x$, i e the equation is then satisfied   Q E D

Examples   VII b

Solve the following equations, giving reasons for each step, and verifying each solution

1   $x=6-2x$ 2 $3x=12+2x$ 3 $4x=42-2x$ 4 $5=16-11x$

19   $9-3x=6+2x-12$ 20 $3x+4+2x+6=0$

[When denominators occur, multiply both sides of the equation by the least common multiple of the various denominators

This operation will clear away the fractions

Thus if $\dfrac{3x-4}{10}=\dfrac{5}{12}$,

multiply both sides by 60,

$$\frac{60}{10}\times(3x-4)=\frac{5}{12}\times60,$$

or $6(3x-4)=25$, $18x-24=25$]

21. $\dfrac{x}{3}=\dfrac{1}{2}$ 22 $\dfrac{2x}{3}=\dfrac{5}{6}$ 23 $\dfrac{7x}{9}=-21$ 24. $\dfrac{2x}{3}-\dfrac{1}{4}=\dfrac{3}{4}$

25   $\dfrac{3}{4}x=-\dfrac{9}{2}$ 26 $\dfrac{5x}{7}=\dfrac{3}{4}$ 27 $\dfrac{3}{4}=-\dfrac{x}{12}$ 28 $\dfrac{x}{4}+\dfrac{17}{8}=0$

29   $\dfrac{11x}{13}-\dfrac{19x}{31}=0$ 30 $\dfrac{x-3}{5}=0$ 31 $\dfrac{2x-5}{7}=0$ 32 $3(x-1)=3$

33   $\dfrac{x-1}{4}=1$ 34. $\dfrac{2x-1}{3}=3$ 35 $\dfrac{3x+5}{7}=2$ 36 $\dfrac{2x}{3}-\dfrac{5}{6}=0$

37   $6(x-3)=0$ 38 $3(x+5)=0$ 39 $\dfrac{2}{3}(x-10)=0$

40   $5(2x-7)=0$ 41 $3(3x+7)=0$ 42 $\dfrac{4}{5}(6x-15)=0$

43   $\dfrac{13}{11}(19x-27x)=0$ 44 $\dfrac{47}{151}\left(\dfrac{x}{2}-1\right)=0$

43 Let us consider the equation $2x + 5 = 10 - 4x$

Adding $4x$ to both sides, $\qquad 2x + 4x + 5 = 10$

[*N B* —The result of this operation is that $-4x$ disappears from the right hand side, and appears on the left, *with its sign changed*]

$$\textit{i e.} \quad 6x + 5 = 10$$

Taking 5 from each side, $\qquad 6x = 10 - 5$

[*N B* —Again, the result is that 5 disappears from the left hand side and appears on the right, *with its sign changed*]

We therefore deduce the following most important rule

Any term may be transposed from one side of an equation to the other by changing its sign

Example 1. Solve the equation $3x - 4 + 5x - 4 = 3x - 10 + 7x + 16$

Transposing so that we have all the terms containing x on the left, and the other terms on the right,

$$3x + 5x - 3x - 7x = -10 + 16 + 4 + 4,$$
$$\textit{i e.} \quad 8x - 10x = 24 - 10,$$
$$-2x = 14$$

Dividing both sides by -2, $\qquad x = -7$, the required solution

Verification. When $x = -7$, the left side

$$= -7 \times 3 - 4 - 7 \times 5 - 4 = -21 - 4 - 35 - 4 = -64.$$

When $x = -7$, the right hand side

$$= -7 \times 3 - 10 - 7 \times 7 + 16 = -21 - 10 - 49 + 16 = -64 = \text{the left hand side}$$

$$\text{Q E D}$$

Example 2 Solve the equation $x^2 - 8x + 23 = x(x - 3) - 2(x - 4) + 3$

Removing the brackets, $x^2 - 8x + 23 = x^2 - 3x - 2x + 8 + 3$

Transposing all the terms containing x, or powers of x, to the left, and other terms to the right,

$$x^2 - 8x - x^2 + 3x + 2x = 8 + 3 - 23,$$
$$\textit{i e.} \quad -8x + 5x = -23 + 11,$$
$$-3x = -12$$

Dividing both sides by -3, $\qquad x = 4$, the required solution

Verification. When $x = 4$,

$$\text{the left hand side} = 4 \times 4 - 8 \times 4 + 23$$
$$= 16 - 32 + 23 = 7$$

When $x = 4$, the right hand side $= 4(4 - 3) - 2(4 - 4) + 3$
$$= 4 + 3 = 7$$
$$= \text{the left hand side} \qquad \text{Q E D}$$

Example 3   Solve the equation

$$(x-1)(x+6)=(x-2)(x-3)+3$$

Multiplying out, $x^2+5x-6=x^2-5x+6+3$

Transposing, $x^2+5x-x^2+5x=6+6+3,$

$$10x=15,$$
$$x=1\tfrac{1}{2}$$

11. $3(2x+5)-4(x-3)=5(3x+1)-4$

12   $11(x-2)-2(4-3x)-4(1-2x)=17(x-1)+7$

13   $x(x+4)=x^2+36$ 14. $(x+3)(x-2)=x^2-26$

17. $2x^2-7=x(2x-3)$ 18 $3x^2-5-x(3x+1)=0$

19   $(x+1)(x+4)=x(x+2)$ 20 $2(x-1)(x+1)=2x^2-4x$

21   $(x-3)^2=x^2+4x+29$ 22 $(x-4)^2=(x-1)^2-3$

23   $(x-2)^2=(x-5)^2-15$ 24. $(x-3)(x+3)=(x+4)(x-7)+40$

25   $x(x-9)-4=(x-7)(x+7)$

26   $2(x-6)(x+6)+12=(2x-1)(x-3)$

44.   When the equations are in fractional form, the fractions should be cleared first

Example 1   Solve the equation $\dfrac{x}{4}+\dfrac{3}{5}=\dfrac{1}{4}-\dfrac{x}{5}+\dfrac{7}{2}$

Multiplying both sides by 20, the L.C.M of 4, 5, and 2,

$$5x+12=5-4x+70$$

Transposing, $5x+4x=5+70-12,$

$$9x=63,$$
$$x=7$$

Example 2   Solve the equation $\dfrac{3}{5}+\dfrac{4}{10x}=\dfrac{23}{5x}+1$

Multiplying both sides by $10x$,

$$3\times 2x+4=23\times 2+10x,$$
$$6x+4=46+10x,$$
$$6x-10x=46-4,$$
$$-4x=42$$

Dividing both sides by -4, $x=-\dfrac{42}{4}=-\dfrac{21}{2}=-10\tfrac{1}{2}$

Verification When $x = -10\frac{1}{2} (= -\frac{21}{2})$,

the left hand side
$$= \frac{3}{5} + \frac{4}{10} - \left(-\frac{21}{2}\right)$$
$$= \frac{3}{5} - \frac{4}{10} \times \frac{2}{21} = \frac{3}{5} - \frac{4}{105}$$
$$= \frac{63-4}{105} = \frac{59}{105}$$

When $x = -10\frac{1}{2}$, the right hand side $= \frac{23}{5} - \left(-\frac{21}{2}\right) + 1$
$$= -\frac{23}{5} \times \frac{2}{21} + 1 = -\frac{46}{105} + 1$$
$$= \frac{-46+105}{105} = \frac{59}{105}$$
$$= \text{the left hand side} \qquad \text{Q E D}$$

Example 3 Solve the equation $\dfrac{x-3}{4} - \dfrac{x-5}{2} = \dfrac{x+1}{8} - \dfrac{x-4}{3}$

Multiplying both sides by 24, the L C M of 4, 2, 8, and 3,
$$6(x-3) - 12(x-5) = 3(x+1) - 8(x-4),$$
$$i\ c \qquad 6x - 18 - 12x + 60 = 3x + 3 - 8x + 32$$

Transposing, $\quad 6x - 12x - 3x + 8x = 3 + 32 + 18 - 60,$
$$i\ e \qquad\qquad -x = -7,$$
$$x = 7$$

Verification When $x = 7$, the left hand side $= \frac{7-3}{4} - \frac{7-5}{2} = 1 - 1 = 0$

When $\qquad\qquad x = 7$, the right hand side $= \frac{7+1}{8} - \frac{7-4}{3}$
$$= 1 - 1 = 0$$
$$= \text{the left hand side} \qquad \text{Q E D}$$

Useful facts to note in connection with decimals.

$$4 \times 25 = 1, \qquad \frac{1}{25} = \frac{4}{4 \times 25} = 4$$

Thus $\dfrac{7}{25} = \dfrac{7 \times 4}{1} = 28$ Also $\dfrac{1}{125} = \dfrac{8}{8 \times 125} = 8$

$$\frac{1}{025} = \frac{40}{40 \times 025} = 40 \qquad \frac{7}{75} = \frac{7 \times 4}{4 \times 75} = \frac{28}{3}$$

Example 4 Solve the equation $\dfrac{x + 15}{125} - \dfrac{x - 25}{25} = 3\ 3$

$$\frac{8(x + 15)}{1} - \frac{4(x - 25)}{1} = 3\ 3,$$
$$8x + 1\ 2 - 4x + 1 = 3\ 3,$$
$$4x = 3\ 3 - 2\ 2,$$
$$4x = 1\ 1,$$
$$x = 275$$

Approximate Solutions.

45　In finding approximate values,
One half or more than one half counts as unity

i.e. ·5	·5	,
·05	·05 and < 1	1
·005	·005 and $< \cdot01$	·01, and so on.

Thus if $x = 3\,74526$

$x = 3\,7$ correct to one dec place,
$= 3\,75$ two dec places,
$= 3\,745$ three ,
$= 3\,7453$ four

In solving the equation $7x = 25$,

dividing both sides by 7, $x = 3\,571428$

$x = 4$,   to the nearest integer,
$= 3\,6$ correct to one dec place,
$= 3\,57$ two   places,
$= 3\,571$ three

Thus, in approximations, if the first figure neglected is 5 or more than 5, increase by one the last figure retained

CHAPTER VIII

SYMBOLICAL EXPRESSION

46. Algebra is largely used for solving problems of various kinds, but before attempting this the beginner must learn how to express given statements symbolically, *i e* in algebraic form

Let us take a few simple cases

There are (3×4) ft in 4 yards

Thus we see that there are $3x$ ft in x yds

There are (20×5) shillings in £5

Hence there are $20x$ shillings in £x

There are (12×7) pence in 7 shillings

There are $12x$ pence in x shillings

Just as 2×6 is a number which is double of 6, so $2a$ represents a number which is double the number represented by a

The number which is 3 greater than 6 is $6 + 3$

The number which is 3 greater than x is $x + 3$

The number which is a greater than x is $x + a$

7 buns at 2 pence each, cost 7×2 pence

Hence x buns at 2 pence each cost $(x \times 2)$ pence, *i e* $2x$ pence

$$235 \text{ shillings} = (235 - 20)\,£\,,$$
$$x \text{ shillings} = (x - 20)\,£$$
$$= \frac{x}{20}\,£$$

14 pounds and 6 shillings are the same as $(14 \times 20 + 6)$ shillings

In the same way x pounds $+ y$ shillings $= (20x + y)$ shillings

6 pounds $+ 5$ shillings $+ 4$ pence $= (6 \times 240 + 5 \times 12 + 4)$ pence

x pounds $+ y$ shillings $+ z$ pence $= (240x + 12y + z)$ pence

If 13 articles cost 54 shillings, each article costs $\frac{54}{13}$ shillings

If x 54 $\dfrac{54}{x}$

x y $\dfrac{y}{x}$

An even number is a number which has 2 for a factor

if x is any whole number,

$2x$ is an even number

if x is any whole number,

$2x + 1$ is an odd number

$2x - 1$ is also an odd number

47 **Example 1** What is the cost of a articles at b shillings each? 12 articles at 3 shillings each cost 12×3 shillings

by analogy, a articles at b shillings each cost ab shillings

Example 2 A man walks x miles in hour How far does he walk in y hours? If he walks 4 miles an hour, he will walk 4×6 miles in 6 hours

by analogy, if he walks x miles an hour, he will walk xy miles in y hours

Example 3 A man has x crowns and y florins, how many shillings has he? x crowns $= 5x$ shillings, and y florins $= 2y$ shillings,

he has $(5x + 2y)$ shillings

Example 4 If I spend x shillings out of £y, how many pence have I left? £$y = 240y$ pence, and x shillings $= 12x$ pence,

I have $(240y - 12x)$ pence left

Substitution in formulae

48 If r is the radius of a circle, and C its circumference, the two quantities r and C are connected by the formula

$$C = 2\pi r, \text{ where } \pi = \tfrac{22}{7}$$

(This is only an approximate value of π)

Thus if we know the radius of a circle, we can find its circumference.

Example 1. Find the circumference of a circle whose radius is 21 feet.

If C denote the circumference, substituting the given value of r in the formula $C = 2\pi r$,

$$C = 2\pi \times 21 \text{ feet}$$
$$= 2 \times \tfrac{22}{7} \times 21 \text{ feet, for } \pi = \tfrac{22}{7},$$
$$= 2 \times 22 \times 3 \text{ feet}$$
$$= 6 \times 22 = 132 \text{ feet.}$$

Example 2 Given that the circumference of a circle is 99 ft. in length, find its radius.

If r denote its radius, $2\pi r = 99$,

$$2 \times \tfrac{22}{7} r = 99,$$
$$r = \frac{7 \times 99}{2 \times 22} = \frac{7 \times 9}{4} \text{ feet}$$
$$= \tfrac{63}{4} = 15\tfrac{3}{4} \text{ feet}$$
$$= 15 \text{ feet 9 inches}$$

The area, A, of the floor of a room whose length is l, and breadth b, is given by the formula

$$A = l \times b$$

Example 3 Find the area of a room $16\tfrac{1}{2}$ feet long and $10\tfrac{1}{2}$ feet wide.

If A denote the area, substituting in the above formula,

$$A = 16\tfrac{1}{2} \times 10\tfrac{1}{2} \text{ sq ft}$$
$$= \tfrac{33}{2} \times \tfrac{21}{2} = \tfrac{99 \times 7}{4} = \tfrac{693}{4} \text{ (multiplying by factors)}$$
$$= 173\tfrac{1}{4} \text{ sq ft}$$

$$= \tfrac{44}{7} \times 6 \text{ inches}$$
$$= \tfrac{264}{7} \text{ inches}$$
$$= 37 \cdot 7 \quad \text{inches}$$
$$= 38 \text{ in} \quad \text{(to the nearest inch)}$$

$$= 28 \cdot 28 \quad \text{sq inches}$$
$$= 28 \cdot 3 \text{ sq in} \quad \text{(to the nearest tenth)}$$

CHAPTER IX
EASY PROBLEMS

49   We will now proceed to solve some easy problems

Example 1.   Three times a certain number diminished by 15 comes to
to 45   find the number

Let x be the number required

Three times the number diminished by 15 is $3x-15$,
$$3x-15=45,$$
$$3x=45+15=60,$$
$$x=20,$$
$$i\ e\ \text{the required number is } 20$$

Verification $3\times20-15=60-15=45$

Example 2   A man is twice as old as his son, and ten years ago he was three times as old   Find the present ages of the father and son

Let x be the present age of the son

Then, by hypothesis, the present age of the father is $2x$ years

10 years ago the son was $x - 10$ years old

Also 10 years ago the father was $2x - 10$ years old

$$2x - 10 = 3(x - 10),$$
$$2x - 10 = 3x - 30,$$
$$2x - 3x = -30 + 10,$$
$$-x = -20,$$
$$x = 20$$

the father is now 40, and the son 20 years old

The student should verify the result.

Example 3   A man paid a bill of £6 10s in sovereigns and florins   If he used three times as many florins as sovereigns, find the number of sovereigns he paid away and the number of florins

Let x be the number of sovereigns he used

Then $3x$ is the number of florins he used

x sovereigns $= 20x$ shillings, and $3x$ florins $= 6x$ shillings

Also £6 10s $= 130$ shillings,

$$20x + 6x = 130,$$
$$26x = 130,$$
$$x = 5,$$

i e he used 5 sovereigns and 15 florins

Example 4   The number 55 is divided into two parts such that one-third of one part, together with one fifth of the other part, is equal to 17   Find the parts

Let x be one part   Then $55 - x$ is the other part

$$\frac{x}{3} + \frac{55 - x}{5} = 17$$

Multiply both sides by 15,

$$5x + 3(55 - x) = 17 \times 15,$$
$$5x + 165 - 3x = 255,$$
$$5x - 3x = 255 - 165,$$
$$2x = 90,$$
$$x = 45,$$
$$\text{and } 55 - x = 55 - 45 = 10$$

45 and 10 are the reqd parts

Example 5   A and B travel in opposite directions from two places 54 miles apart, and meet in 6 hou   If A goes twice as fast as B, find their rates of travelling

Suppose B travels x miles an hour   then A travels $2x$ miles an hour

In 6 hours, B goes $6x$ miles,

A goes $12x$ miles

But the total distance travelled by A and B in 6 hours is 54 miles.

$$6x + 12x = 54,$$
$$x = 3,$$

i e A travels 6 miles an hour, and B 3 miles an hour

USE OF SQUARED PAPER

[The most convenient paper for beginners is that ruled to show inches and tenths of an inch]

50 *To find the length of a straight line joining the corners of any two squares, with the aid of a pair of compasses*

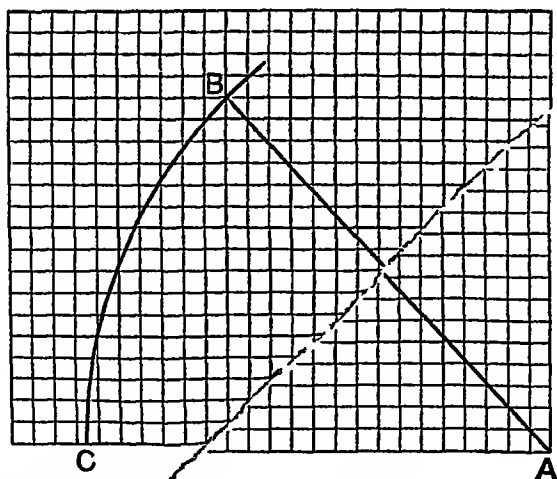

Take points A and B at corner of squares
With centre A and radius AB describe an arc of a circle cutting ➤

the horizontal line through A at C　We see that the point C falls as nearly as possible at the middle point of a side of a small square

Therefore, from the diagram AB = AC = 2 15 inches

51　*A man travels 8 miles due east, then 9 miles north, then 15 miles west, and finally 14 miles south　Find to the nearest half-mile his distance at the finish from the starting point*
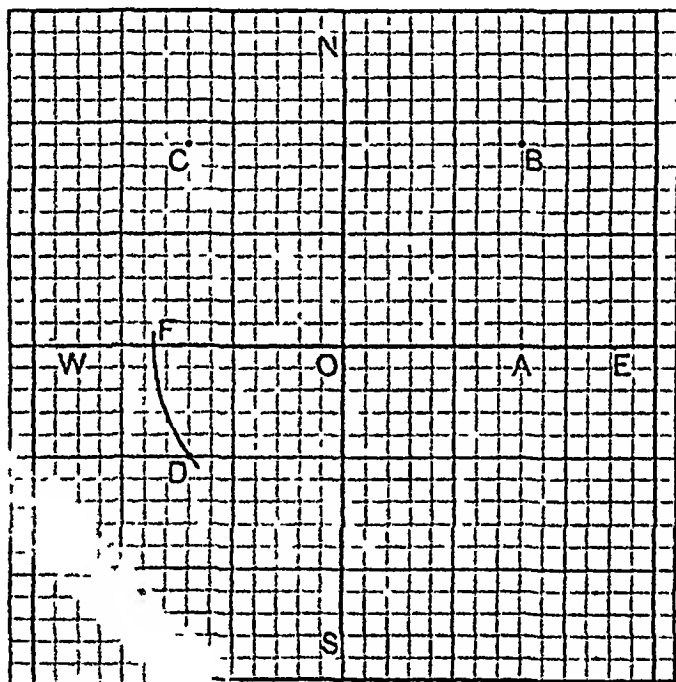

Using a side of each square to represent one mile, with the accompanying diagrams, first takes him from O to A,

9 m sou h	A to B,
15 m west	B to C,
and 11 m sout	C to D

With centre O and radius OD describe a circle cutting the line OW at F　The req'd distance = OD = OF　miles to the nearest half-mile, from the diagram

52 *Two vertical posts, 16 ft and 26 ft high, are 40 ft apart*
Find, to the nearest foot, the length of the straight wire joining their
upper ends
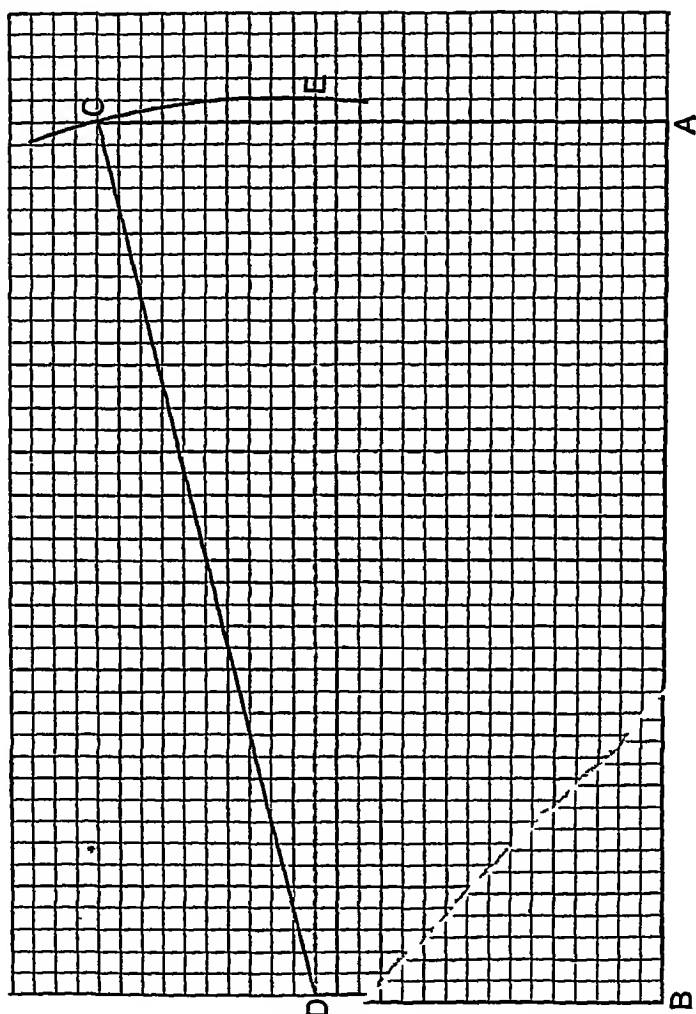

Taking one-tenth of an inch to represent one foot, one inch
will represent 10 feet

Mark the points A and B 4 inches apart, also the point C 2 6
inches vertically above A, and the point D 1 6 inches vertically
above B   Join CD

$AB = 4$ inches and therefore represents 40 feet
$AC = 2\,6$ inches　　　　　　　　26 feet
$CD = 1\,6$ inches　　　　　　　　16 feet

Therefore CD represents the wire whose length is required
With centre D and radius DC, describe an arc of a circle to cut the
horizontal line through D at E

From the diagram we see that $DE = 4\,1$ inches

$DC = 4\,1$ inches, and the wire is $10 \times 4\,1$, i.e. 41 feet long

53 *A ladder 30 ft long has its foot at a distance of 10 feet from
a vertical wall　How far up the wall does it reach ?*
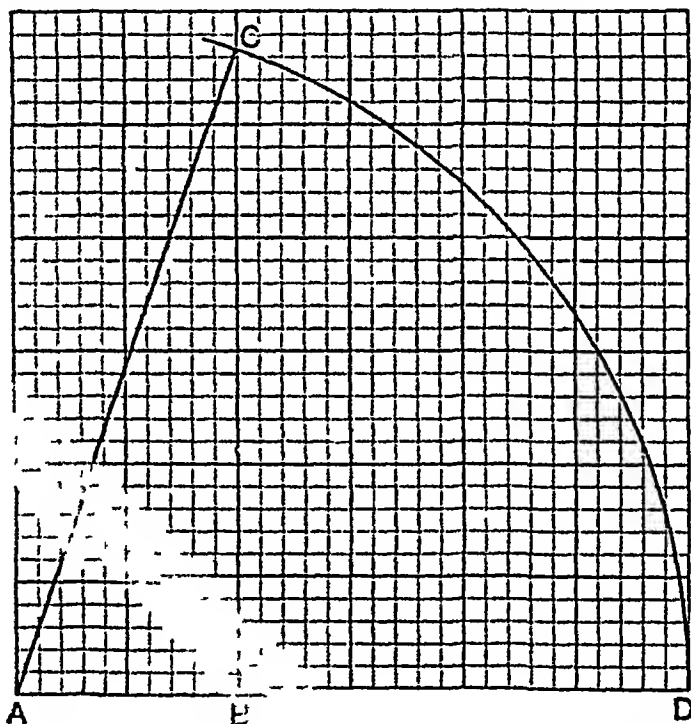

Let A be the foot of the ladder, and, taking a side of a square
to represent one foot, take B 10 units in a horizontal line from A,
so that B is the foot of the wall

With centre A and radius 30 units, describe a circle to cut the
vertical through B at C

AC represents 30 feet so that C is the point in the wall to which the ladder reaches

From the diagram it is seen that BC the required distance = 28 3 feet   Here we estimate the decimal of a foot by eye

54 *Two sides of a triangle contain a right angle and are 1 6, and 1 2 feet long respectively   to find, by means of squared paper, the length of the third side*
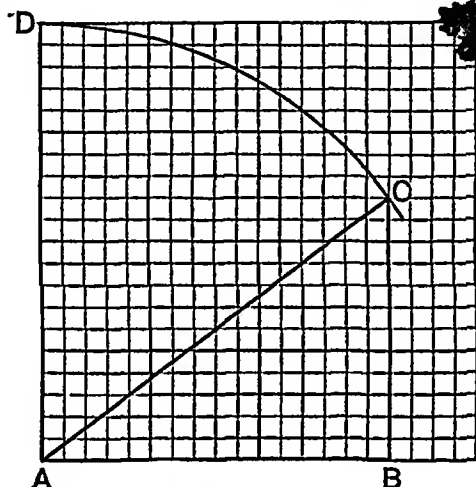

Taking an inch to represent a foot, AB 1 6 in long represents the longer side, and BC at right angles to it and 1 2 in long represents the shorter side   Join AC

With centre A and radius AC, describe an arc of a circle cutting the vertical line through A at D

AC = AD = 2 in from the diagram

       the side required is 2 feet long

Those who are familiar with the proposition in geometry which proves that "the square on the hypotenuse of a right-angled triangle is equal to the sum of the squares on its sides" can readily verify the above as follows

$$AC^2 - AB^2 = 2^2 - 1 6^2 = (2 + 1 6)(2 - 1 6)$$
$$= 3 6 \times 4$$
$$= 1 44 = 1 2^2 = BC^2$$
$$\therefore\ AC^2 = AB^2 + BC^2$$

CHAPTER X

SIMULTANEOUS EQUATIONS OF THE FIRST DEGREE IN TWO UNKNOWNS

57 Take the equation $3x - 4y = 12$

$$3x = 4y + 12 \qquad x = \frac{4y + 12}{3}$$

For every value we give to y, we get a corresponding value of x

Thus, if $y = 1$, $\qquad x = \frac{4 + 12}{3} = \frac{16}{3}$,

if $y = 2$, $\qquad x = \frac{8 + 12}{3} = \frac{20}{3}$,

if $y = 3$, $\qquad x = \frac{12 + 12}{3} = 8$,

if $y = -2$, $\qquad x = \frac{-8 + 12}{3} = \frac{4}{3}$, and so on

Hence we see that the equation $3x - 4y = 12$ has an infinite number of solutions, $i\,e$ an infinite number of values of x and y can be found which will satisfy the equation

But suppose we are given two equations,

$$3x - 4y = 12, \tag{1}$$
$$5x + 2y = 46 \tag{2}$$

We can now find values of x and y which will satisfy *both* equations

From (1) $3x = 4y + 12$, $\qquad x = \frac{4y + 12}{3}$

,, (2) $5x = 46 - 2y$, $\qquad x = \frac{16 - 2y}{5}$

Hence, if the value of x is the same in both equations,

$$\frac{4y + 12}{3} = \frac{16 - 2y}{5}$$

Multiplying both sides by 15, $\quad 5(4y + 12) = 3(46 - 2y)$

$$20y + 60 = 138 - 6y$$
$$26y = 78,$$
$$y = 3$$

Substituting this value of y in equation (1),

$$3x - 4 \times 3 = 12,$$
$$3x = 24,$$
$$x = 8$$

Thus the values $x = 8$, $y = 3$, will satisfy both equations

Verification   When $x = 8$, and $y = 3$,

$$3x - 4y = 3 \times 8 - 4 \times 3 = 12$$

equation (1) is satisfied

Again, when $x = 8$, and $y = 3$, $5x + 2y = 5 \times 8 + 2 \times 3 = 46$

equation (2) is also satisfied   Q E D

58 We notice in the above, that in order to find the value of y we first get rid of x

This process of getting rid of an unknown quantity is called *elimination*

We might have effected the above solution by eliminating y and obtaining the value of x first   We should then obtain the value of y by substituting this value of x in one of the original equations

Also we notice that having first found the value of y, we may substitute that value in either equation   It is advisable, of course, to choose the simpler equation for this substitution

If we put $y = 3$ in equation (2), we have

$$5x + 2 \times 3 = 46,$$
$$5x = 46 - 6 = 40,$$
$$x = 8, \text{ as before}$$

Also we must observe that two simultaneous equations of the first degree have only one solution

59 The following method of elimination is the most common

Example 1   Solve the simultaneous equations,

$$3x + 5y = 31, \tag{1}$$
$$2x + 7 = 34 \tag{2}$$

Multiplying (1) by 7, $21x + 35y = 203,$

      „   (2) by 5, $10x + 35y = 170$

(N B —*The coefficients of y in the two equations are now equal.*)

Subtracting $11x = 33,$
$$x = 3$$

Substituting this value of x in equation (1),

$$3 \times 3 + 5y = 29,$$
$$5y = 29 - 9 = 20,$$
$$y = 4$$
$$\left.\begin{matrix} x = 3 \\ y = 4 \end{matrix}\right\} \text{ is the reqd solution}$$

Verification   When $x = 3$ and $y = 4$, $3x + 5y = 3 \times 3 + 5 \times 4 = 29$
$$2x + 7y = 2 \times 3 + 7 \times 4 = 34$$

Example 2   Solve the simultaneous equations,

$$3x + 2y = 2,$$
$$5x - 2y = -18$$

(N B —The coefficients of y are equal *but of opposite sign*)

Adding, $8x = -16,$
$$x = -2$$

Substituting this value of x in either equation we obtain the value of y
This is left as an exercise for the student

The work may often be shortened if the coefficients of x or y have common factors

Example 3   Solve the simultaneous equations,

$$38x + 17y = 127, \tag{1}$$
$$133x + 71y = 479 \tag{2}$$

These equations may be written,

$$2 \times 19x + 17y = 127,$$
$$7 \times 19x + 71y = 479$$

Multiplying (1) by 7, $266x + 119y = 889,$
Multiplying (2) by 2, $266x + 142y = 958$
Subtracting, $-23y = -69,$
$$y = 3$$

Substituting this value of y in equation (1),

$$38x + 51 = 127,$$
$$38x = 76,$$
$$x = 2$$
$$\left.\begin{matrix} x = 2 \\ y = 3 \end{matrix}\right\} \text{ is the reqd solution}$$

60　If necessary first simplify the equations

Example 1　Solve the equations,

$$\frac{x+y}{3}=2+2y, \qquad (1) \qquad \frac{2x-4y}{5}=1\frac{1}{5}-y \qquad (2)$$

Multiplying (1) by 3, and simplifying,

$$x+y=6,$$
$$x-5y=6 \qquad\qquad (3)$$

Multiplying (2) by 5, and simplifying,

$$2x-4y=23-5y,$$
$$2x+y=23 \qquad\qquad (4)$$

We now solve equations (3) and (4) in the usual manner,

Example 2   Solve the equations,

$$\frac{2}{x}-\frac{3}{y}=3, \tag{1}$$

$$\frac{5}{x}+\frac{6}{y}=48 \tag{2}$$

In such cases as this, it is advisable to solve first for $\frac{1}{x}$ and $\frac{1}{y}$

Thus, multiplying (1) by 2, $\quad\frac{4}{x}-\frac{6}{y}=6$

Adding this to (2), $\quad\frac{9}{x}=54$

$$\frac{1}{x}=6,$$

$$x=\tfrac{1}{6}$$

Substituting this value of x in (2), $5\times6+\frac{6}{y}=18,$

$$\frac{6}{y}=48-30=18,$$

$$\frac{1}{y}=3,$$

$$y=\tfrac{1}{3}$$

$$\left.\begin{array}{l}x=\tfrac{1}{6}\\y=\tfrac{1}{3}\end{array}\right\}\text{ is the required solution}$$

SIMULTANEOUS EQUATIONS WITH THREE UNKNOWN QUANTITIES

61   The method is similar to that for solving equations with two unknowns   Here however we shall need *three* equations

Example 1   Solve the equations, $2x+3y-z=5,$ (1)

$$x-y+2z=1,\qquad (2)$$

$$6y+5z=7\qquad (3)$$

First let us eliminate z from equations (1) and (2)

Multiplying (1) by 2, $4x+6y-2z=10$

Adding (2), $3x-4y+2z=\ 1$

$$\overline{7x+2y\qquad =11}\qquad (4)$$

Next eliminate z from equations (1) and (3)

Multiplying (1) by 5 $\qquad$ $10x+15y-5z=25$

Adding (3), $\qquad$ $4x-6y+5z=\ \ 7$

$$14x+9y\qquad=32 \tag{5}$$

Now let us solve equations (4) and (5)

Multiplying (4) by 2, $\qquad$ $14x+4y=\ \ 22$

Subtracting (5), $\qquad$ $14x+9y=\ \ \ 32$

$$-5y=-10$$
$$y=2$$

Substituting this value of y in (4), $\qquad$ $7x+4=11,$
$$7x=7,$$
$$x=1$$

Substituting *for both x and y* in equation (1),

$$2+6-z=\ \ 5,$$
$$-z=-3,$$
$$z=\ \ 3$$

$$\left.\begin{array}{l}x=1\\y=2\\z=3\end{array}\right\}\text{ is the reqd solution}$$

Example 2   Solve the equations $\dfrac{1}{x}+\dfrac{1}{y}=7,$ $\qquad$ (1)

$$\frac{2}{x}-\frac{3}{z}=-9, \tag{2}$$

$$\frac{3}{y}+\frac{4}{z}=32. \tag{3}$$

Here we shall first solve for $\dfrac{1}{x}$, $\dfrac{1}{y}$ and $\dfrac{1}{z}$

First eliminate $\dfrac{1}{z}$ from (2) and (3)

Multiplying (2) by 4, $\qquad$ $\dfrac{8}{x}-\dfrac{12}{z}=-36$

(3) by 3, $\qquad$ $\dfrac{9}{y}+\dfrac{12}{z}=\ \ 96$

Adding, $\qquad$ $\dfrac{8}{x}+\dfrac{9}{y}=\ \ 60$

Multiplying (1) by 9, $\qquad$ $\dfrac{9}{x}+\dfrac{9}{y}=\ \ 63$

Subtracting, $\qquad$ $-\dfrac{1}{x}=-3,$

$$\frac{1}{x}=3,$$
$$x=\frac{1}{3}$$

Substituting for x in equation (1), $3+\dfrac{1}{y}=7,$

$$\frac{1}{y}=4,$$
$$y=\tfrac{1}{4}.$$

Substituting for y in equation (3),

$$3 \times 4 + \frac{4}{z} = 32,$$

$$3 + \frac{1}{z} = 8,$$

$$\frac{1}{z} = 5,$$

$$z = \tfrac{1}{5}$$

$$\left. \begin{array}{l} x = \tfrac{1}{3} \\ y = \tfrac{1}{4} \\ z = \tfrac{1}{5} \end{array} \right\} \text{ is the reqd solution}$$

Example 3   Solve the equations $\frac{x}{3} = \frac{y}{8} + 1 = \frac{z}{2} - 3$,

$$\frac{y}{2} - \frac{z}{5} = 2$$

From the first equation $\dfrac{x}{3} = \dfrac{y}{8} + 1$

Multiplying both sides by 24, $8x = 3y + 24,$

$$8x - 3y = 24 \tag{1}$$

Also from the first equation $\dfrac{y}{8} + 1 = \dfrac{z}{2} - 3$

Multiplying both sides by 8, $y + 8 = 4z - 24,$

$$y - 4z = -32 \tag{2}$$

Multiplying both sides of $\dfrac{y}{2} - \dfrac{z}{5} = 2$ by 10,

$$5y - 2z = 20 \tag{3}$$

Multiplying by 2, $10y - 4z = 40$

Subtracting (2), $\underline{y - 4z = -32}$

$$9y = 72$$
$$y = 8$$

Substituting this value of y in equation (1),

$$8x - 24 = 24$$
$$x = 6$$

Substituting for y in equation (2),

$$8 - 4z = -32,$$
$$-4z = -40,$$
$$z = 10$$

$$\left. \begin{array}{l} x = 6 \\ y = 8 \\ z = 10 \end{array} \right\} \text{ is the reqd solution}$$

CHAPTER XI

BRACKETS.

62. When two or more pairs of brackets occur within one another the best plan is to remove the *outermost* first. After a little practice, several pairs may be removed in one step

Example 1   Prove that $8a - \{3a + (2a - 5)\} = 3a + 5$

(In removing the curly bracket we must look upon all the terms in the plain bracket as a single quantity)

$$\begin{aligned} \text{The given expression} \quad &= 8a - 3a - (2a - 5) \\ &= 5a - 2a + 5 \\ &= 3a + 5 \qquad\qquad \text{Q E D} \end{aligned}$$

Example 2   Simplify $3\{6x - 2(2x - 1)\}$

[Every term inside the curly brackets must be multiplied by 3, and each term inside the plain brackets must be multiplied by 2 *as well*]

$$\begin{aligned} \text{The given expression} \quad &= 18x - 6(2x - 1) \\ &= 18x - 12x + 6 \\ &= 6x + 6 \end{aligned}$$

Examples XI a

Prove the following

(Remove one pair of brackets at a time)

1 $a - \{b - (c + d)\} = a - b + c + d$ 2 $6a - \{2a + (a - 5)\} = 3a + 5$

3 $4a - \{3a - (2a - a)\} = 2a$ 4 $7x + \{2x - (3x - 4)\} = 6x + 4$

5 $a - \{a - (a - a)\} = 0$ 6 $3 - \{4x - (2x + 4) + 1\} = 6 - 2x$

7 $9x + \{3x - (4x - 2) + x\} = 9x + 2$ 8 $7 - \{4x + (2x - 3) + 7\} = 3 - 6x$

9 $14 - \{12 - (2x - 6) - 9x\} = 11x - 4$

10 $12x - \{3x - (7x - 9) + (2x - 3)\} = 14x - 6$

11 $24 - \{5x - (2x + 5) - (3x - 7)\} = 22$ 12 $2\{x + 3(x - 2)\} = 8x - 12$

13 $3\{7x - 2(3x - 4)\} = 3x + 24$ 14 $4\{3a - (a - 2a)\} = 16a$

15 $2 - 3\{x - 2 - 5(x - 1)\} = 12x - 7$

16 $6 - 2\{x - 3 - (x + 4) + 3(x - 2)\} = 32 - 6x$

17 $7\{2 - 3(x - 4) + 4(x - 6)\} = 7x - 70$ 18 $6\{x - \frac{1}{2}(x - 1)\} = 3x + 3$

19 $8\{2x - \frac{1}{4}(6x + 5)\} = 4x - 10$ 20 $6\{x - \frac{1}{3}(2x - 7) + \frac{1}{2}(x - 5)\} = 5 - 1$

Simplify the following, removing both pairs of brackets in one step

21 $3x + \{2x - (x + 2)\}$ 22 $6 - \{5 - (3 - x)\}$ 23 $2x - \{x - (x - 2)\}$

24 $6x + \{5 - (2x - 5)\}$ 25 $9 - \{-2 + (2x - 7)\}$ 26 $a - \{b - (c - d)\}$

27 $a + [2a - (7a - 1) - (9 - 8a)]$ 28 $6y - [3x - (2y - x) + (3y - 5x)]$

29 $9a - [3b + (2a - 5b) - (3a + 5b)]$ 30 $11c + [-3d - (3c - 3d) + c]$

31 $a - [-(a - b) + (a + b)]$ 32 $2\{3x + 3(x - 1)\}$

33 $3\{2x - 5(2x - 3)\}$ 34 $7\{x - 2(3 - x)\}$

35 $3\{6a - 5(a - 1)\}$ 36 $2\{3x - 1 - 3(a - 7)\}$

37 $4\{a - 2(a - 1) + 3(a - 2)\}$ 38 $3\{x - 3(a - 1) - (1 - a)\}$

39 $2x - 7\{3 - (2x - 1) - 2(x - 2)\}$ 40 $x - 3\{y - 2(3x + y) + (3y - x)\}$

63 **Example 1**   Prove that $a - [3b - \{4a - (a - b)\}] = -2a + 2b$

$$\text{The given expression} \quad = a - [3b - \{4a - (a - b)\}]$$

(In removing the square bracket [ ] we must look upon all the terms within the curly brackets as a single quantity)

$$= a - 3b - 4a + (a - b)$$

[Regarding $(a - b)$ as a single quantity as before]
$$= a + 3b - 4a + a - b$$
$$= 2a - 4a + 3b - b$$
$$= -2a + 2b$$

Or, more shortly, the given expression
$$= a + 3b - 4a + a - b$$
$$= 2a - 4a + 3b - b$$
$$= -2a + 2b$$

This is easy to understand if we remember that the plus preceding the square bracket does not alter the minus preceding the curly bracket, whilst the minus preceding the curly bracket changes the minus preceding the plain bracket into plus

Example 2 Simplify the expression
$$4[a - 3\{a - 2(b - c) + 2c\} - 4(a - b)]$$
Every term inside the square brackets must be multiplied by 4
Every term inside the curly brackets must be multiplied by 3 *as well*
Also $(b - c)$ must be multiplied by 2 as well as by 3 and 4
$(a - b)$ must be multiplied by 4×4

The given expression
$$= 4a - 12\{a - 2b + 2c + 2c\} - 16(a - b)$$
$$= 4a - 12a + 24b - 24c - 24c - 16a + 16b$$
$$= -24a + 40b - 18c.$$

Example 3
$$a - 2b - [3a - 5b - \{2a - 3c + (5a - 2c - \overline{3a - b + 2c})\}]$$
$$= a - 2b - 3a + 5b + 2a - 3c + 5a - 2c - 3a + b - 2c$$
$$= 2a + 4b - 7c.$$

Explanation. The minus preceding the first square bracket ([) operating on the minus preceding the first curly bracket ({) makes it plus

Thus the plus in front of the first plain bracket remains plus and the minus preceding the vinculum remains minus

The work of the above might be given in greater detail thus
The given expression
$$= a - 2b - 3a + 5b + \{2a - 3c + (5a - 2c - \overline{3a - b + 2c})\}$$
$$= a - 2b - 3a + 5b + 2a - 3c + (5a - 2c - \overline{3a - b + 2c})$$
$$= a - 2b - 3a + 5b + 2a - 3c + 5a - 2c - \overline{3a - b + 2c}$$
$$= a - 2b - 3a + 5b + 2a - 3c + 5a - 2c - 3a + b - 2c$$
as before

Examples   XI b.

Remove the brackets and collect the like terms in the following expressions

1   $4a - \{3a - (2a - a)\}$ 2 $a - [a - (a - \overline{a - c})]$

3   $a - \{a + (a - \overline{a + b})\}$ 4. $2x - [3x - \{5x - (5x - 6x) + 2x\}]$.

5   $7 + [6 - 2(3 + x) - 4(x - 2)]$ 6 $4a - 3[a - 4(1 - a)]$

14. $-[-\{-(-x)\}] - [-\{-(-x - y)\}]$

Prove the following

15   $3b - \{5a - [6a + (12a - 3b)] - a\} = 14a$

16   $9(b - c) - [-\{a - b - 4(c - b + a)\}] = -3a + 12b - 13c$

17   $5x^2 - (3x - \overline{x^2 - 4}) + 2(x^2 - \overline{x - 5}) = 8x^2 - 5x + 6$

18   $4a - [2a - \{2b(x + y) - 2b(x - y)\}] = 2a + 4by$

When $a = 1$, $b = 2$, $c = 0$, prove that

21   $3bc - [4ab + \{3a - (12a - 7b) - 2abc\}] = -13$

22. $4[a - 2(b - c) - \{a - (b - 2)\}] = -16$

Express the following in their simplest forms

23   $7a - [5b - \{4a - (3a - 2b)\}]$

24. $a - (b - c) - \{b - (a - c)\} - [a - \{2b - (a - c)\}]$

25   $a - [3a + c - \{4a - (3b - c)\} + 3b]$

26   $5a - [2a - 2\{a - (a - 1)\} + 2]$ 27 $6a - [3b - \{2a - (6a - 3b)\}]$

28   $a - [3b + \{3c - 2a - (a - b)\} + 2a - (b - 3c)]$

29   $3\{a - 2[b - 4(c - d)]\} - 4\{a - 3[b + 4(c + d)]\}$

30   $a - [2a - \{3a - (4a - \overline{5a - 7})\}]$

31   $4x^2 - 2x(x - 2y) + 2y(2y + x) - 2x^2$

32   $2[3ab - a\{-b + b(2 + a)\} + 3\{a(2 - b) + a^2b\}]$

33   $x^3 - 2x\{x^2 - x(2 - x)\} + 3[x^3 - x(x - 1)]$

34. $3a - 2[3a - 2\{3a - 2(3a - \overline{2a + b}) + b\} + b]$

35   $5a - 4[2a - 3\{4a - \overline{3a - b}\} - 4b] + 24a$

36   $4\{4 - 4(4 - a) + a\} - 3\{a - 3(a - 3) + a\}$

37   $3[xy + x\{y - y(3 + x)\} + 2\{x(3 - y) - x\}]$

38   $x - x[x + x(x - \overline{1 - x})]$

Prove the following

39   $\frac{3x - 1}{4} - \frac{2 - x}{5} + \frac{1}{5} = \frac{1}{2}$,   when

40 $\dfrac{6}{x-1}=\dfrac{5}{x-2}$, when $x=7$ 41 $\dfrac{5}{3x-2}-\dfrac{19}{7x-1}=0$, when $x=\frac{3}{4}$

42 $\dfrac{7}{x-2}-\dfrac{4}{x+1}=0$, when $x=-12$

43 $\dfrac{2(x+1)}{5}-8=\dfrac{2x}{10}-1$, when $x=24$

44. $\dfrac{x-4}{5}-\dfrac{x-5}{6}=\dfrac{x-2}{24}$, when $x=14$

45 $x-1-\dfrac{x^3+3}{x+2}=0$, when $x=5$

46 $\dfrac{6x+1}{x+1}-\dfrac{3+6x^2}{x^2-1}=-1\frac{2}{3}$, when $x=2$.

Insertion of brackets

64. In the preceding articles we have dealt with the removal of brackets   Sometimes it is necessary to insert brackets, and the rules for doing so will obviously be the converse of the rules for their removal

Any number of terms may be placed within brackets with the positive sign ($+$) prefixed, without changing the signs of the terms included in the brackets

Any number of terms may be placed within brackets with the negative sign ($-$) prefixed, provided that the sign of each term included in the brackets is changed

Thus $2a+3b-4c-5d=2a+(3b-4c-5d)$

Also the same expression $=2a+3b-(4c+5d)$

$ac-bd+bc-ad=ac-(bd-bc+ad)$

$=ac-(bd-bc)-ad$

When all the terms within a pair of brackets have a common factor, that common factor may be removed and placed outside the bracket as a multiplier

$$4a-(5a-5d)=4a-5(a-d)$$
$$x^3-(2x^2-4x+6)=x^3-2(x^2-2x+3)$$

Example   Collect in brackets the like powers of x in the expression
$$ax^3-cx^2-dx-bx^3-dx^2+ax$$

The given expression
$$=ax^3-bx^3-cx^2-dx^2-dx+ax$$
$$=x^3(a-b)-x^2(c+d)-x(d-a)$$

11.　$ax^4 - bx^3 - cx^2 - px^4 + qx^3 + rx^2$

12　$3(m+n)x^2y - 2mxy^2 - 2(m-n)x^2y + 2nxy^2$

Bracket the powers of x in the following expressions so that the signs preceding the brackets are all negative

13　$ax^3 + px^2 - qx + c - bx^3 - cx^2 - dx - p$

14　$ax^2 - bx - c - bx^3 - bx^2 + cx + d - ax^3$

15　$ax^2 - (a-1)x + 2a + (3-2a)x - bx^2$

65　Identities　An equation which is true for all values of the symbols used is called an identity

The symbol $\equiv$ is often used to denote that two expressions are identically equal, i e that they are equal for all values of the symbols used

Thus when we write $a - b \equiv -b + a$, we mean that $a - b$ and $-b + a$ are equal whatever values we assign to the symbols a and b

Example 1　Prove the truth of the following identity

$$4a - \frac{2a-b}{3} + \frac{4a+4b}{6} \equiv 4a + b$$

$$4a - \frac{2a-b}{3} + \frac{4a+4b}{6} \equiv 4a - \frac{2a}{3} + \frac{b}{3} + \frac{4a}{6} + \frac{4b}{6}$$

$$\equiv 4a - \frac{2a}{3} + \frac{2a}{3} + \frac{b}{3} + \frac{2b}{3}$$

$$\equiv 4a + b \qquad\qquad \text{Q E D}$$

To prove the truth of an identity when both sides of the equation are somewhat complicated it is often advisable to simplify each side separately

Example 2 Prove the truth of the identity

$$3x - y + 4\left[x - \left(3y - x - \frac{2x-4}{2} \right) \right] \equiv 5(x - y - 1) - 4(y - x) - 4y + 6x - 3$$

$$3x - y + 4\left[x - \left(3y - x - \frac{2x-4}{2} \right) \right] \equiv 3x - y + 4x - 4(3y - x - x + 2)$$

$$\equiv 3x - y + 4x - 12y + 8x - 8$$

$$\equiv 15x - 13y - 8 \tag{1}$$

Again, taking the right hand side,

$$5(x - y - 1) - 4(y - x) - 4y + 6x - 3 \equiv 5x - 5y - 5 - 4y + 4x - 4y + 6x - 3$$

$$\equiv 15x - 13y - 8 \tag{2}$$

from (1) and (2),

$$3x - y + 4\left[x - \left(3y - x - \frac{2x-4}{2} \right) \right] \equiv 5(x - y - 1) - 4(y - x) - 4y + 6x - 3$$

Q E D

Example 3 Simplify the expression $x - 5 - [3 + \{x - (3 + x)\}]$, and hence determine what value of x will make it equal to zero

The given expression

$$= x - 5 - 3 - x + 3 + x$$

$$= x - 5,$$

it is equal to zero when $x = 5$

Example 4 Prove that $\frac{7x}{2} - \frac{x-8}{3} - \frac{1}{5}(4x+2) \equiv \frac{32-x}{30}$

$$\frac{7x}{2} - \frac{x-8}{3} - \frac{4}{5}(4x+2) \quad \text{(The L C M of 2, 3 and 5 is 30)}$$

$$\equiv \frac{15 \times 7x}{15 \times 2} - \frac{10(x-8)}{10 \times 3} - \frac{6 \times 4(4x+2)}{6 \times 5}$$

$$\equiv \frac{105x - 10x + 80 - 96x - 48}{30}$$

$$\equiv \frac{105x - 10x - 96x + 80 - 48}{30}$$

$$\equiv \frac{32 - x}{30}$$

Q E

Example 5 Find the simplest form of the expression

$$\frac{x-1}{5} - \frac{2x-3}{4} + \frac{3x-1}{2}$$

The L C M of 5, 4 and 2 is 20

the given expression $= \dfrac{4(x-1)}{4 \times 5} - \dfrac{5(2x-3)}{5 \times 4} + \dfrac{10(3x-1)}{10 \times 2}$

$$= \frac{4x - 4 - 10x + 15 + 30x - 10}{20}$$

$$= \frac{24x + 1}{20}$$

CHAPTER XIII

CO ORDINATES, AND GRAPHS OF STRAIGHT LINES

[All graphs should be drawn on squared paper It should be ruled to show inches and tenths of an inch, or centimetres and millimetres]

66 Take two straight lines, XOX', YOY', at right angles to one another Let P be any point in their plane, and draw PN, PM perpendicular to XOX' and YOY' respectively

Let PM = x, and PN = y

These values, x and y, determine the position of the point P, $i\,e$ if we know the values of x and y, we can draw the point P

For instance, if $x = 5$, and $y = 3$, along OX measure ON = 5, and along OY measure OM = 3 units of length Then PM = ON = 5, and PN = OM = 3, and therefore P is the point we required to find
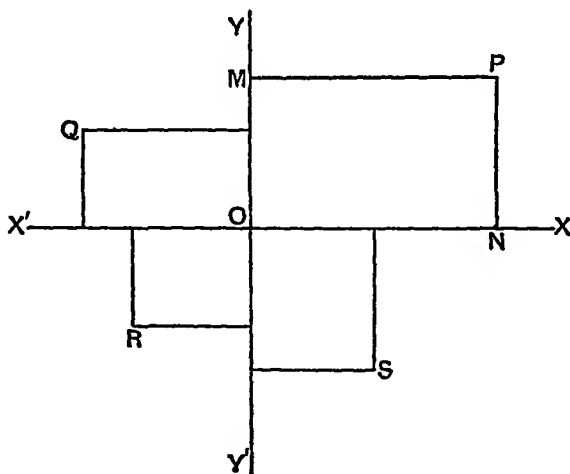

x and y are called the *co ordinates* of the point P, XOX', YOY' the *axes of co ordinates*, or, more shortly, the *axes*, O the *origin*

P is often described as the point (x, y)

x is called the *abscissa*, and y the *ordinate* of the point P

If lines drawn in one direction are taken as positive, then lines drawn in the opposite direction must be taken as negative

Lines drawn in the directions OX, OY are usually considered positive, and therefore lines drawn in the directions OX', OY' are taken as negative

For example, in the accompanying diagram, at Q the abscissa is negative, and the ordinate positive   At R the abscissa is negative, and also the ordinate   At S the abscissa is positive and the ordinate negative

In practice, it is simplest to draw the point (5, 3) in the following way

Along OX measure ON = 5, and at N draw NP perpendicular to ON in the direction OY, the positive direction, and make NP = 3   We then have the same point as in the paragraph above

Example 1   Plot the point (6, 8) and find its distance from the origin

Draw axes XOX', YOY', and using a side of each square as unit, take ON = 6 units along OX

Along the vertical line through N, and *in the positive direction*, take NA = 8 units

A is the point (6, 8)

With centre O and radius OA describe a circle cutting OX at B

The distance reqd $=OA=OB=10$ units, as we see from the diagram

Example 2   Plot the points $(6, 8)$ $(-6, 3)$, and find the length of the line joining them

Plot the pt $(6, 8)$ (See diagram in above example)

Along OX' take OM$=6$ units, and along the vertical line through M, and in the positive direction, take MC$=3$ units

C is the pt $(-6, 3)$

With centre A and radius AC, describe a circle cutting the horizontal line through A at the point D

The length reqd $=AC=AD=13$ units, as we see from the diagram

We might also find the length of AC in the following manner

From the diagram,   AK$=5$ units, and CK$=12$ units
$$AC^2=AK^2+CK^2=5^2+12^2=169,$$
$$AC=13 \text{ units}$$

Example 3   To find the area of the triangle formed by joining the points $(4, 8)$, $(9, -5)$,$(-7, -5)$

[The area of a triangle is equal to one half the product of its base and altitude]

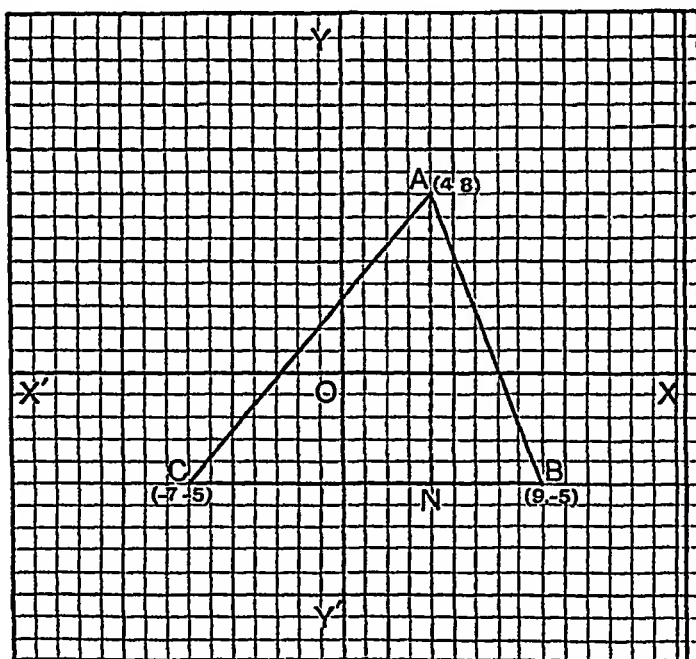

Plot the points as shown in the diagram, and form the triangle ABC, by joining them

We see that the base BC$=16$ units

Also if the vertical line through A meets the base at N, AN is the altitude of the triangle, and is equal to 13 units

the area of the $\triangle = \frac{1}{2}BC \times AN = \frac{1}{2} \times 16 \times 13 = 8 \times 13 = 104$ square units

Example 4. To find the area of a triangle by counting squares

Find the area of the triangle joining the points (7, 6), (−6, 7), (3, −8)
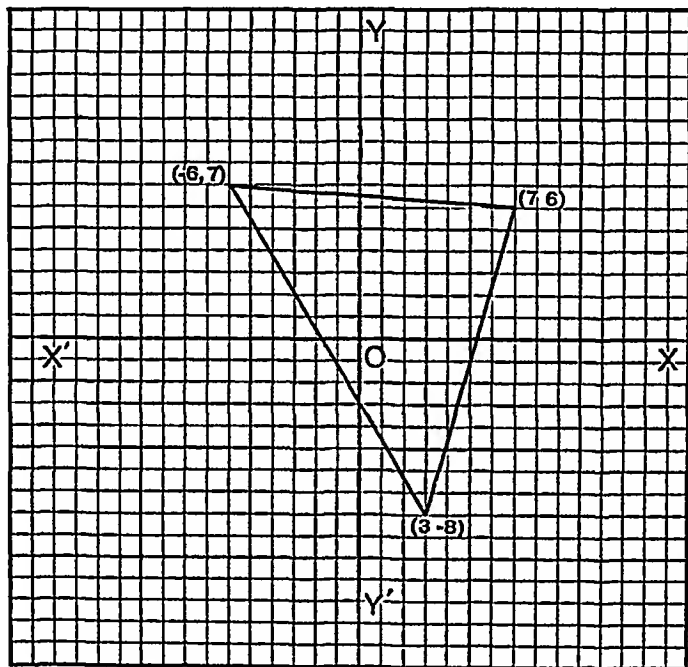

Plot out the points as shown in the diagram, and form the triangle

Now let us count up the number of squares in the triangle, counting as whole squares those which are equal to or greater than half a square, and ignoring those which are less than half a square

Beginning with the top horizontal row, the numbers in the different rows are 7, 12, 11, 10, 9, 9, 8, 6, 6, 5, 4, 3, 2, 1

Adding these up, the total number of squares is 93

the area of the triangle is 93 square units

When one side of a rectilineal figure is drawn along a line of squared paper, its area can easily be found by dividing the figure into rectangles and right-angled triangles

Example 5　Find the area of the figure ABCD in the diagram
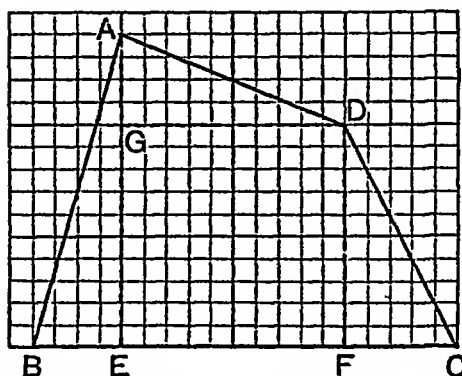

Draw AE and DF perpendicular to BC, and DG perpendicular to AE.

$$\triangle\ ABE = \tfrac{1}{2}BE \times AE = \tfrac{1}{2} \times\ 4 \times 14 =\ 28\ \text{sq units}$$
$$\triangle\ AGD = \tfrac{1}{2}AG \times GD = \tfrac{1}{2} \times\ 4 \times 10 =\ 20$$
$$\triangle\ DFC = \tfrac{1}{2}DF \times FC = \tfrac{1}{2} \times 10 \times\ 5 =\ 25$$
$$\text{Fig DFEG} =\ DF \times EF =\quad 10 \times 10 = \underline{100}$$

the area of ABCD　　　　　$= \overline{173}$ sq units

Example 6　To find the area of the figure ABCD in the diagram
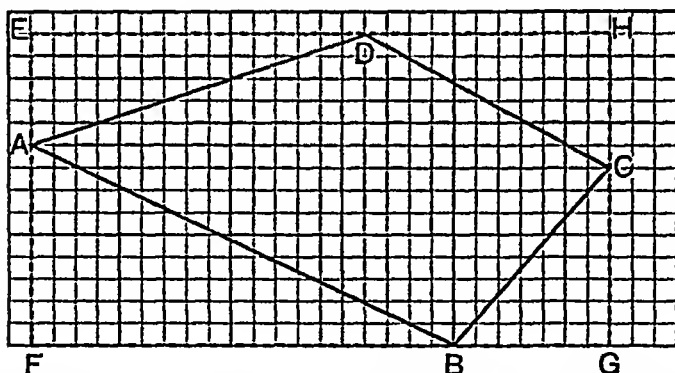

Through A, B, C, D, draw lines along the lines of the paper so as to form the rectangle EFGH

$$\triangle\ AED = \tfrac{1}{2}AE \times DE = \tfrac{1}{2} \times\ 5 \times 15 =\ 37\tfrac{1}{2}\ \text{sq units}$$
$$\triangle\ AFB = \tfrac{1}{2}AF \times BF = \tfrac{1}{2} \times\ 9 \times 19 =\ 85\tfrac{1}{2}$$
$$\triangle\ BGC = \tfrac{1}{2}BG \times CG = \tfrac{1}{2} \times\ 7 \times\ 8 =\ 28$$
$$\triangle\ DHC = \tfrac{1}{2}DH \times CH = \tfrac{1}{2} \times 11 \times\ 6 = \underline{33}$$
$$184$$

$$ABCD = EF \times FG - 184\ \text{sq units}$$
$$= 14 \times 26 - 184$$
$$= 364 - 184$$
$$= 180.$$

31 (5, 12), (−15, 8), (−4, 17)   32 (10, 7), (3, 16), (−8, 3)

67. Draw axes XOX', YOY', and mark a number of points whose abscissae are equal to 6 taking any convenient unit of length

A, B, C, D, E, in the diagram, are such points

We thus see that all points, whose abscissae are equal to 6, lie on the straight line parallel to OY and distant 6 units from it

Moreover, if we look at any other point *not on this line*, we see that its abscissa is *not equal to* 6   In other words, $x=6$ for all points on the straight line CE, and for no other points

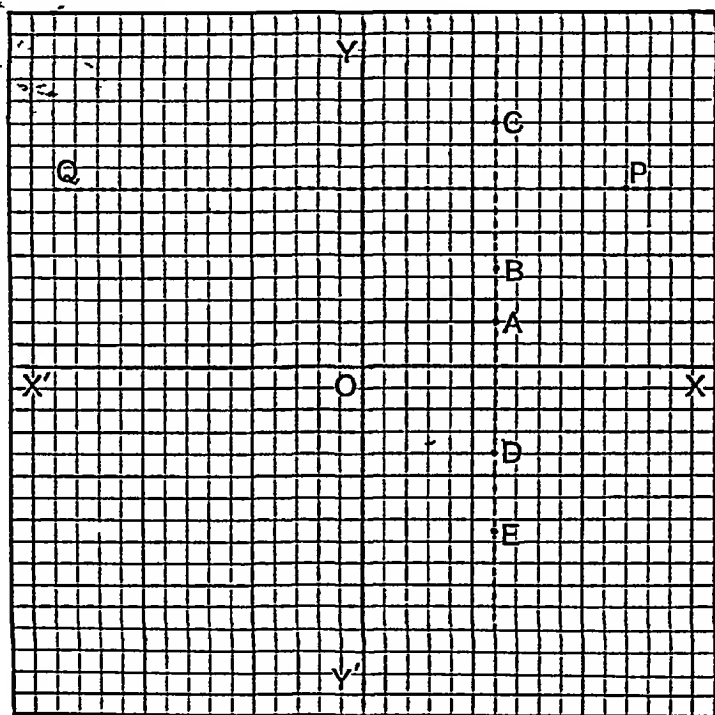

The line CE is therefore called the graph of $x=6$

We notice too that the equation $x=6$ is true for all points on the line however far we produce it in either direction

In the same way, if we mark a number of points whose ordinates are all equal to 8 and join them, we get a straight line PQ parallel to OX, and *it is the graph of* $y=8$

68 If in a diagram we mark the points (2, 2), (3, 3), (4, 4), (5, 5) and so on, and join them, we get a straight line   Also if

(x, y) be the co-ordinates of any point on this line, we see that $x = y$ Hence this line is the graph of $x = y$
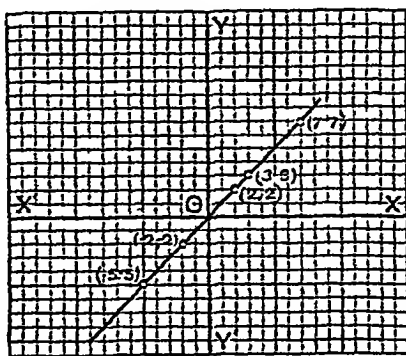

It will be seen that the points $(0, 0)$, $(-1, -1)$, $(-2, -2)$, $(-3, -3)$, etc, all lie on this graph

69   *Draw the graph of* $y = 2x$
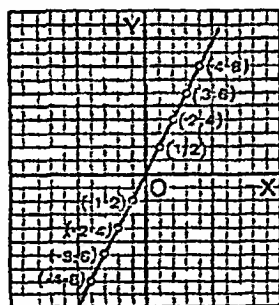

When

$x = 1$	2	3	4	
$y = 2$	4	6	8	

When

$x = 0$	-1	-2	-3	-4	
$y = 0$	-2	-4	-6	-8	

Joining the points thus found, we have the graph required It will be seen to be *a straight line through* **O** *the origin*

N B —The line is of unlimited length

70 *Draw the graph of the expression* $2x - 3$

N B —This is the same as the graph of $y = 2x - 3$
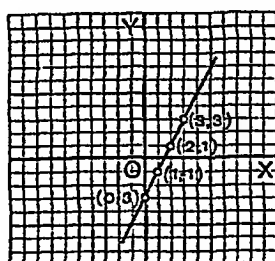

Let $y = 2x - 3$

When

$x = 0$	1	2	3	
$y = -3$	-1	1	*3*	

Marking in a diagram the points thus found, and joining them, we have the graph reqd

It will be seen that the graph is a straight line of unlimited length

71 *Draw the graph of the expression* $\dfrac{2x - 3}{5}$

Let $y = \dfrac{2x - 3}{5}$

When

$x =$	0	1	2	3	4
$y =$	-6	-2	$\cdot 2$	6	1

Marking these points in a diagram and joining them, we have the graph reqd

N B —It will be seen that all graphs of expressions of the first degree, i e graphs obtained from equations of the first degree, are straight lines

72 *To draw the graph of the expression* $\dfrac{26 - 2x}{5}$, *i e the graph of the equation* $y = \dfrac{26 - 2x}{5}$

[The equation being of the first degree, its graph is a straight line It will therefore be sufficient if we plot two points on the

graph, for only one straight line can be drawn through two given points]
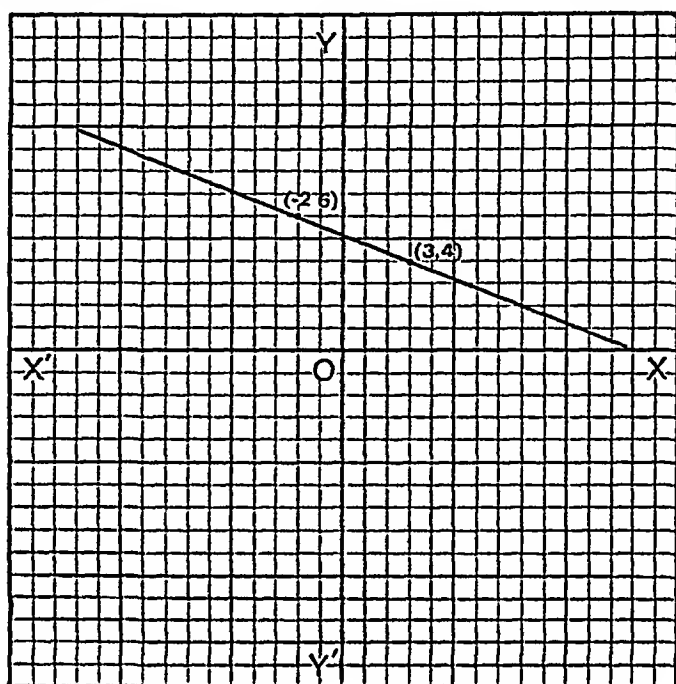

Choose convenient points

When $\qquad x = 3, \quad y = \dfrac{26 - 6}{5} = 4$

the pt (3, 4) is on the graph

When $\qquad x = -2, \quad y = \dfrac{26 + 4}{5} = 6$

the pt (−2, 6) is also on the graph

Joining these points, P and Q in the diagram, the line PQ is the graph reqd

73 *Solve graphically, on squared paper, the following equations*

$$2x - y = 11 \quad x - 2y = 10$$

In the first equation, when $y = 1$, $x = 6$ Mark this pt on the squared paper

In the same equation, when $y = 3$, $x = 7$.   Mark this pt also

The str line joining these pts is the graph of the first equation

In the second equation, when $y = 1$, $x = 12$ Mark this pt in the same diagram

Also in the second equation, when $y = 2$, $x = 14$ Mark this pt

The line joining these last two pts gives the graph of the second equation
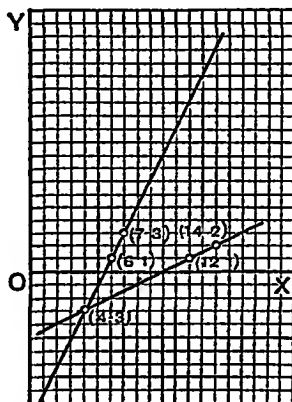

From the diagram it will be seen that the str lines meet at the pt $(4, -3)$

Hence $x = 4$, $y = -3$, is the reqd solution

Verification   In the first equation, when

$$x = 4,   2 \times 4 - y = 11,$$
$$-y = 11 - 8 = 3, y = -3$$
$$x = 4, y = -3 \text{ satisfy the first equation}$$

In the second equation, when $x = 4$,

$$4 - 2y = 10, -2y = 10 - 4,$$
$$y = -3$$
$$x = 4, y = -3 \text{ satisfy this equation also}$$

74. The following are very important

(1) The co-ordinates of the origin are $(0, 0)$

(2) If a point lies on the axis of x, its ordinate is zero

(3) If a point lies on the axis of y, its abscissa is zero

Thus we see that the graph of $x = 0$ is the axis of y, and the graph of $y = 0$ is the axis of x

(4) The graph of $x=a$, where a is constant, is a str. line ∥ to the axis of y

The student should illustrate this by drawing graphs of $x=2$, $x=5$, $x=-7$, and so on

(5) The graph of $y=b$, where b is constant, is a str line ∥ to the axis of x

Illustrate this by drawing the graphs of $y=3$, $y=4$, $y=-8$

75 It is sometimes advisable to work with other units than an inch, or a tenth of an inch

Draw the graph of $\dfrac{3x-7}{6}$
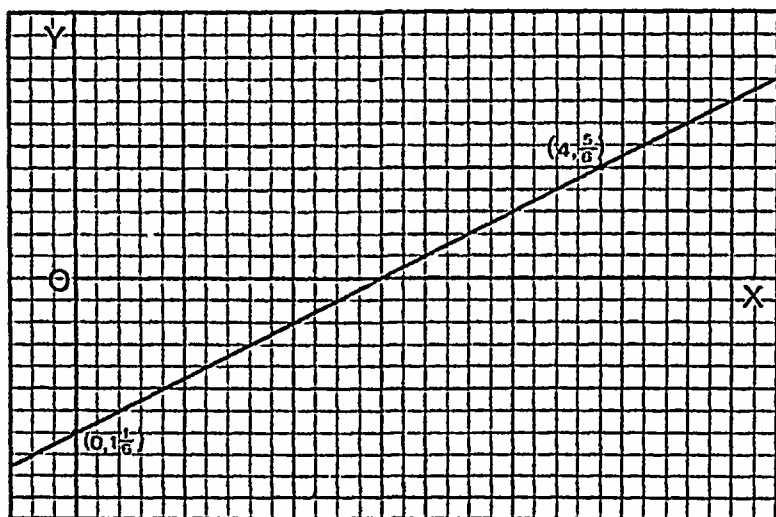

Let $y=\dfrac{3x-7}{6}$ The graph is a str line since the equation is of the first degree   When

$x=$	0	4
$y=$	$-\frac{7}{6}$	$\frac{5}{6}$

Taking 6 tenths of an inch to represent unity, we have the graph as shown in the diagram

76 *To find the equation of the graph which passes through the points*
   (2, 3)(4, 1 5)(6, 0)(8, − 1 5)(10, − 3)

[In the diagram 10 sides of a small square are taken to represent unity]
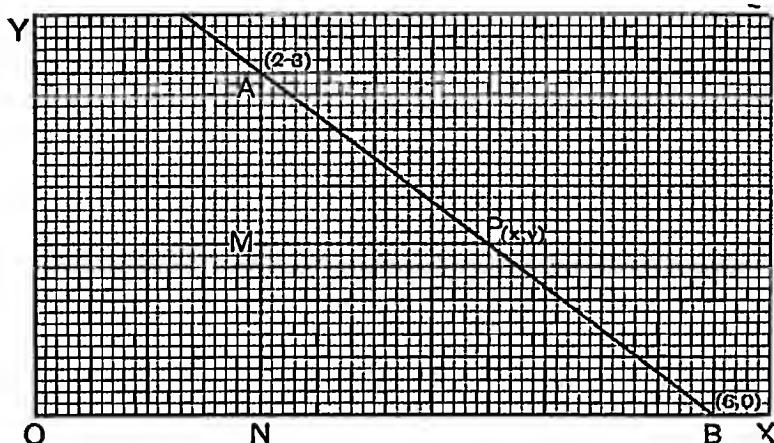

When we plot these points we see that they lie in a str line
   the equation of the graph is of the first degree

Let $ax + by = c$ be the equation reqd

The pt (2, 3) is on the graph,

$x = 2$, $y = 3$ satisfy the equation $ax + by = c$,

   i e $2a + 3b = c$. (1)

The pt (6, 0) is on the graph,

$x = 6$, $y = 0$ satisfy the equation $ax + by = c$,

   i e $6a = c$,

$$a = \frac{c}{6}$$

. from (1) $3b = c - \dfrac{c}{3} = \dfrac{2c}{3}$,

$$b = \tfrac{2}{9}c$$

$$\frac{cx}{6} + \frac{2cy}{9} = c,$$

   i e $3x + 4y = 18$ is the equation reqd

The equation might also be found as follows

Let P (x, y) be any pt on the line

△s AMP, ANB are equiangular, and therefore their sides are proportional

$$\frac{AM}{PM} = \frac{AN}{BN},$$

$$\text{i e} \quad \frac{3-y}{x-2} = \frac{3}{4} \quad \text{(see diagram)}$$

CHAPTER XIV

PROBLEMS INVOLVING SIMULTANEOUS EQUATIONS

77   **Example 1**   Find two numbers such that twice the first added to three times the second is equal to 45, and also such that five times the first added to four times the second is equal to 74

Let x be the first number, and y the second

Twice the first $+3$ times the second $=2x+3y$,

$$2x+3y=45, \text{ (by hypothesis)} \qquad (1)$$

5 times the first $+4$ times the second $=5x+4y \qquad (2)$

$$5x+4y=74, \text{ (by hypothesis)}$$

Multiplying (1) by 4, $8x+12y=180,$ (3)

(2) by 3, $15x+12y=222$ (4)

Subtracting (3) from (4), $7x=42,$

$$x=6$$

Substituting this value of x in (1),

$$2\times6+3y=45,$$
$$3y=45-12=33,$$
$$y=11$$

6 and 11 are the reqd numbers

Verification. $2\times6+3\times11=12+33=45,$

$$5\times6+4\times11=30+44=74$$

Example 2   Five years ago A was twice as old as B, and 6 years hence their united ages will come to 82   Find their present ages

Let x years be A's present age, and y years B's present age

5 years ago, A's age was $x-5$, and B's age $y-5$

by hypothesis, $x-5=2(y-5),$

$$x-5=2y-10,$$
$$x-2y=-5, \qquad (1)$$

6 years hence, A's age will be $x+6$ years, and B's age $y+6$,

by hypothesis, $x+6+y+6=82,$

$$x+y=70, \qquad (2)$$

Subtracting (1) and (2) $-3y=-75,$

$$y=25$$

Substituting in (1), $x-50=-5,$

$$x=45$$

A's present age is 45, and B's 25

In representing numbers of more than one digit algebraically, we must remember that 23 means $2\times10+3$, and not 2×3

Thus the number, whose tens' digit is x and units' digit y, is $10x+y$, and not xy, for xy denotes $x\times y$

Example 3   The sum of the digits of a certain number, less than 100, is 11, and if the digits are reversed, the number is diminished by 9   Find the number

Since the number is less than 100, it has two digits

Let x be the tens' digit, and y the units' digit

By the first hypothesis, $x + y = 11$ (1)

The number obtained by reversing the digits is $10y + x$

by the second hypothesis, $10x + y - (10y + x) = 9,$

$$10x + y - 10y - x = 9,$$

$$9x - 9y = 9,$$

$$x - y = 1$$ (2)

Adding (1) and (2), $2x = 12,$

$$x = 6$$

Substituting this value in (1), $y = 5$

the reqd number is $10 \times 6 + 5 = 65$

Verification.   The sum of the digits $= 6 + 5 = 11,$

$$65 - 56 = 9$$

Example 4.   A man walks two thirds of a journey at 4 miles an hour, then bicycles back for one quarter of the whole journey at 8 miles an hour, and turning round, runs the rest of the way, taking 9 hours over the whole journey   If he had run the whole distance at the rate at which he did the last part, he would have taken $4\frac{4}{7}$ hours   find his rate of running

Let a miles be the whole distance, and suppose he ran x miles per hour

He walks 4 miles in 1 hour ,

$\qquad$ 1 mile in $\frac{1}{4}$ hour ,

$\qquad$ $\dfrac{2a}{3}$ miles in $\dfrac{2a}{3} \times \dfrac{1}{4} = \dfrac{a}{6}$ hours   (1)

He bicycles 8 miles in an hour ,

$\qquad$ 1 mile in $\frac{1}{8}$ hour ,

$\qquad$ $\dfrac{a}{4}$ miles in $\dfrac{a}{32}$ hours   (2)

His distance now from the end of his journey

$$= a - \frac{2a}{3} + \frac{a}{4} = \frac{7a}{12}$$

He runs x miles an hour ,

$\qquad$ 1 mile in $\dfrac{1}{x}$ hour ,

$\qquad$ $\dfrac{7a}{12}$ miles in $\dfrac{7a}{12x}$ hours   (3)

From (1), (2), (3), $\dfrac{a}{6} + \dfrac{a}{32} + \dfrac{7a}{12x} = 9$

Simplifying this, $19a + 56\dfrac{a}{x} = 864$ (4)

He runs x miles in an hour,

a miles in $\dfrac{a}{x}$ hours,

$$\frac{a}{x}=4\frac{4}{7}=\frac{32}{7} \qquad (5)$$

Substituting this value of $\dfrac{a}{x}$ in (4),

$$19a + 8 \times 32 = 864,$$

whence $\qquad\qquad\qquad a = 32$ miles

From (5), $\qquad\qquad\qquad x = \dfrac{7a}{32} = 7$ miles an hour

EASY GRAPHICAL PROBLEMS

78 *A man, starting at noon, walks at the rate of* 6 *miles an hour Draw a graph of his motion, and from the diagram, read off, as accurately as you can, the time when he is* 22 *miles from his starting point, and the distance he has travelled in* 2 *hours* 24 *minutes*

Measure distance along OX, taking a side of each square to represent a mile Measure times along OY, at right angles to OX, taking 10 sides to represent an hour, so that each side represents 6 minutes

Taking OA along OX equal to 30 miles, (30 squares), and AB at right angles to OA equal to 5 hours, (50 squares), B represents the man's position in 5 hours, for he travels 30 miles in 5 hours

Join OB OB is the graph of his motion

By this we mean that any ordinate PN represents the time taken to walk the distance represented by the abscissa ON

To find the time when he is 22 miles from the start, take ON equal to 22 miles and draw the corresponding ordinate NP

This ordinate represents the time reqd

Drawing PK parallel to OX, and *estimating* the value of the portion KV of the side of a square, we see that the reqd time is 3 40 p m

To find the distance travelled at 2 24 p m, take OM along OY equal to 2 hours 24 minutes, and draw MQ parallel to OX.   Draw
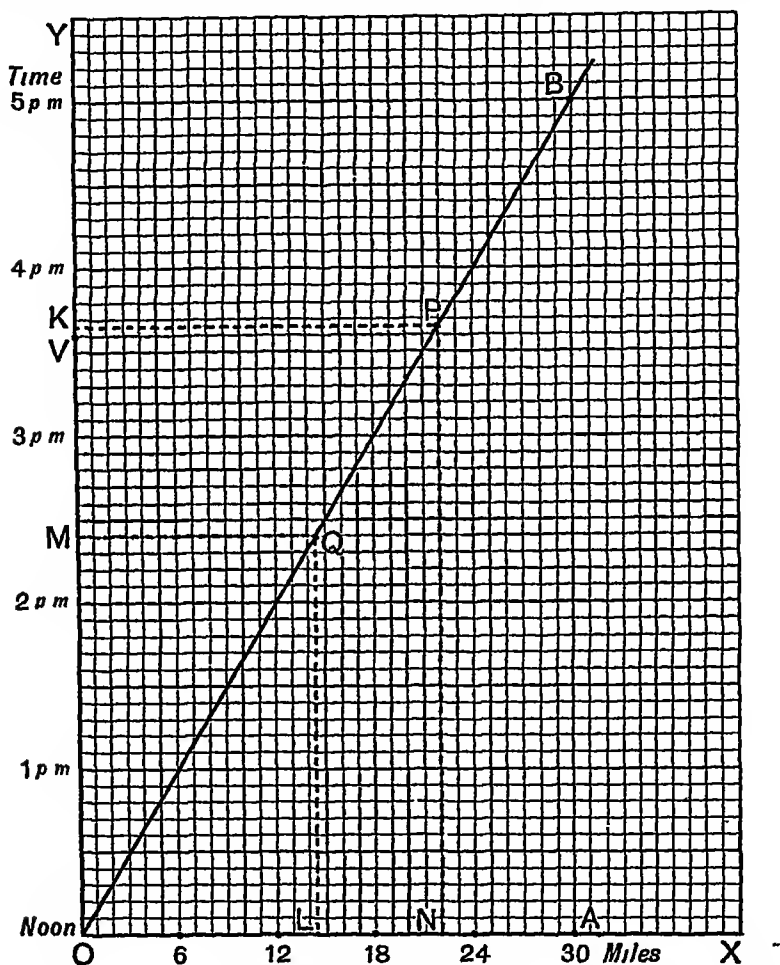

the ordinate QL at Q, OL represents the distance reqd, and is equal to 14½ miles nearly

The student should verify these results by calculation

He should also verify the fact that OB is the graph of the man's motion by taking simple distances, and reading off the corresponding times, *e g* 6 miles (time 1 hour), 12 miles (2 hours) and so on

79 *Given that* 62 *of an English mile* = 1 *kilometre, construct a graph from which you can read off any number of miles in kilometres and any number of kilometres in miles   From it write down the number of kilometres in* 420 *miles and the number of miles in* 580 *kilometres   Calculate the results to the nearest* 10 *kilometres or miles*

If r miles = y kilometres, $\dfrac{r}{62} = \dfrac{y}{100}$

Take an abscissa ON = 62 units (31 sides of a sq),

   and an ordinate NP = 100 units (50   „   „   )

Join OP   OP is the graph of $\dfrac{r}{62} = \dfrac{y}{100}$

   taking each horizontal side of a sq to represent 20 miles,
and each vertical side of a sq to represent 20 kilometres,
   the abscissa of the pt Q represents 420 miles,
      its ordinate represents 420 miles in kilometres
   from the diagram 420 miles = 680 kilometres nearly
Also from the diagram 580 kilometres = 360 miles

80 *Construct a graph which will enable you to convert, at sight, degrees Fahrenheit into degrees Centigrade, and vice versa*

Let $x°$ in the Centigrade scale be the same temperature as $y°$ in the Fahrenheit scale
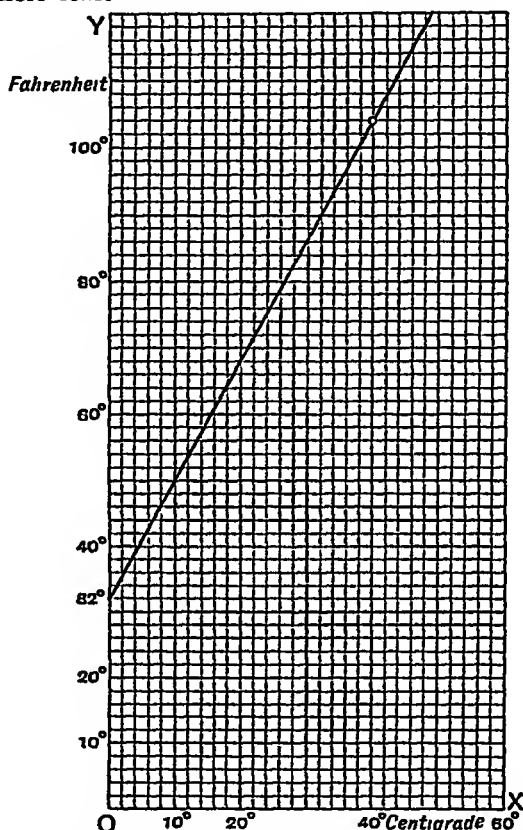

In the Centigrade scale, freezing point stands at 0°, in the Fahrenheit at 32°

In the Centigrade scale, boiling point is at 100°, in the Fahrenheit at 212°

$$\frac{x}{100} = \frac{y - 32}{212 - 32},$$

whence $\qquad\qquad 9x = 5y - 160$

Therefore if we draw the graph of this equation, the abscissae will give us temperatures in Centigrade scale, whilst the corresponding ordinates will give us the corresponding temperatures in Fahrenheit scale

Thus from the graph,

$$80° \text{ F} = 26 \text{ 7}° \text{ C} \text{ and } 40° \text{ C} = 104° \text{ F}$$

A graph may often be drawn without the use of an equation, but the student must realize that every graph has its corresponding equation, and *vice versa*, every equation will have its corresponding graph

81 *Two men start at noon to walk the one from* A *to* B, *the other from* B *to* A *If* A *and* B *are 20 miles apart, and the men walk at the rate of 3 miles an hour and 2 miles an hour respectively, construct a graph which will enable you to determine when and where they meet*

Read off from the graph their distance apart at 1 30 p m and also find at what time they are first at a distance of 6 miles from one another
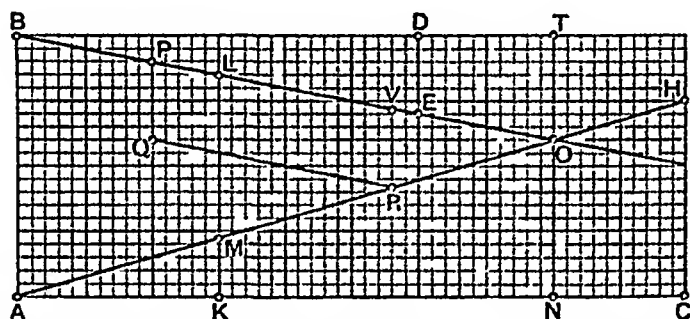

On squared paper, take pts A and B on a vertical line 20 units apart Horizontally take AC = 50 units (10 units to an hour) and vertically CH = 15 units Join AH Then since the first man walks 15 miles in 5 hours (50 units), AH is the graph of the first man's motion, *i e* the ordinate of any pt on AH denotes the distance he has walked in the time denoted by the abscissa of the pt

Considering the second man, take BD horizontally 30 units in length, to denote 3 hours, and DE vertically downwards 6 units in length Join BE

Then BE is the graph of the second man's motion if we read his times along BD, and his distances walked at right angles to BD and downwards

Hence if AH and BE meet at O, AN denotes the time when they meet, and ON, OT denote the distances walked by the two men in that time

Thus from the diagram, we read off that they meet at 4 o clock, that the first man has then walked 12 miles and the second 8 miles

If AK denotes $1\frac{1}{2}$ hours, and KML is drawn vertically, LM is their distance apart at 1 30 p m   From the diagram LM = 12 5 miles

To find when the men are first 6 miles apart, take a pt P on BE where it passes through a corner of a square, and take PQ vertically downwards equal to 6 units

Draw QR ‖ to BE to meet AH at R   If the ordinate through R meet BE at V VR = PQ = 6 units

the abscissa of R gives the time reqd   From the diagram we read this off as 2 8 hrs after noon, i e at 48 minutes after 2 o'clock

82 A *walls a distance of 24 miles at the rate of 4 miles an hour, and B, starting an hour later, does the distance in 3 hours less   Draw graphs of their motion, and from the diagram determine* (1) *when and*
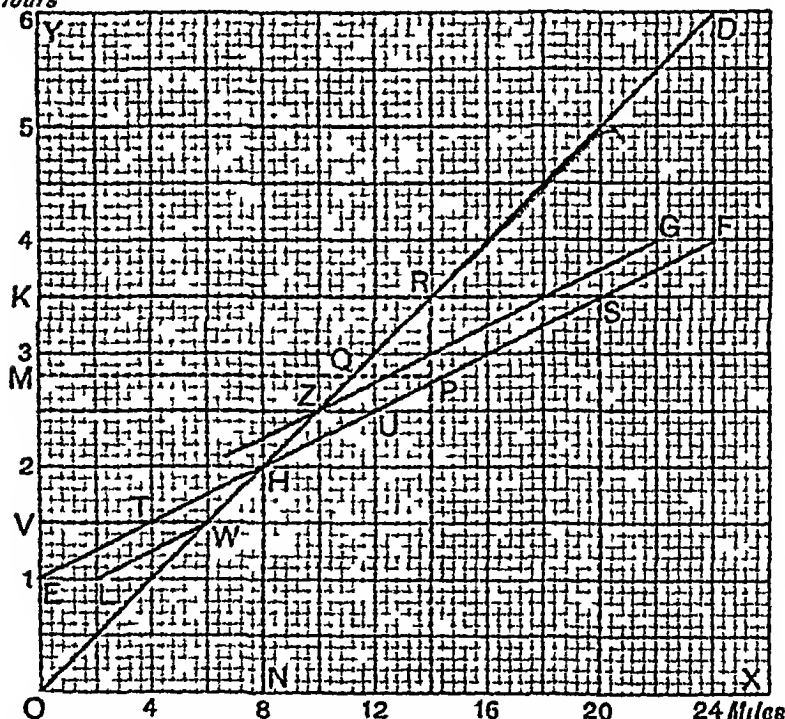

where B overtakes A, (2) *their distance apart after B has been walking 2½ hours,* (3) *the times when they are 2 miles apart*

Measure distances horizontally from O along OX, taking 10 sides of a square to represent 4 miles

Measure times vertically from O along OY, taking 10 sides of a square to represent one hour

Take the point D whose abscissa is 24 miles and ordinate 6 hours

Join OD   OD is the graph of A's motion, for he walks 24 miles in 6 hours

Take the point E at the one hour point in OY   This is B's starting time

Take the point F, whose abscissa is 24 m and ordinate (reckoned from the level of E) 2 hrs less than the time represented by the ordinate of D   Join EF

EF is the graph of B's motion, for he walks the 24 miles in 2 hrs less than A

The coordinates ON, HN of the pt H, where OD and EF intersect, give the place and time of meeting

Thus we see that B overtakes A 8 miles from the start, and one hour after B's start

Looking at the horizontal line PQM, we see that

PM represents the distance walked by B in time OM,

QM   A

PQ represents their distance apart at the time OM

taking K in OY so that EK = $2\frac{1}{2}$ hrs and drawing the horizontal line KRS, RS represents their distance apart when B has been walking $2\frac{1}{2}$ hours   From the figure we see that RS = 6 miles

To determine when they are 2 miles apart, we have to find the point, or points, where the horizontal distance between the graphs represents 2 miles

Taking EL horizontally equal to 2 miles, draw LW ∥ to EF to meet OD at W   Draw WTV horizontally

WT = EL = 2 miles   EV represents the time after B's start when they are 2 m apart

From the figure EV = half an hour

Taking the point G, 2 m horizontally from F, draw GZ ∥ to EF to meet OD at Z

Draw the horizontal line UZ to meet EF at U

UZ = GF = 2 miles and we see from the diagram that the corresponding time is $1\frac{1}{2}$ hours from B's start   they are again 2 m apart in $1\frac{1}{2}$ hours after B's start

This problem should be studied carefully

The beginner must draw a figure for himself, using an inch to represent 4 miles, and one hour

83 *P motors at 16 m an hour, starting at noon and stopping for half an hour at the end of each hour , Q, starting at 2 30 p m motors, without stoppages, at 10 m an hour   When, and at what time does he pass P ?*
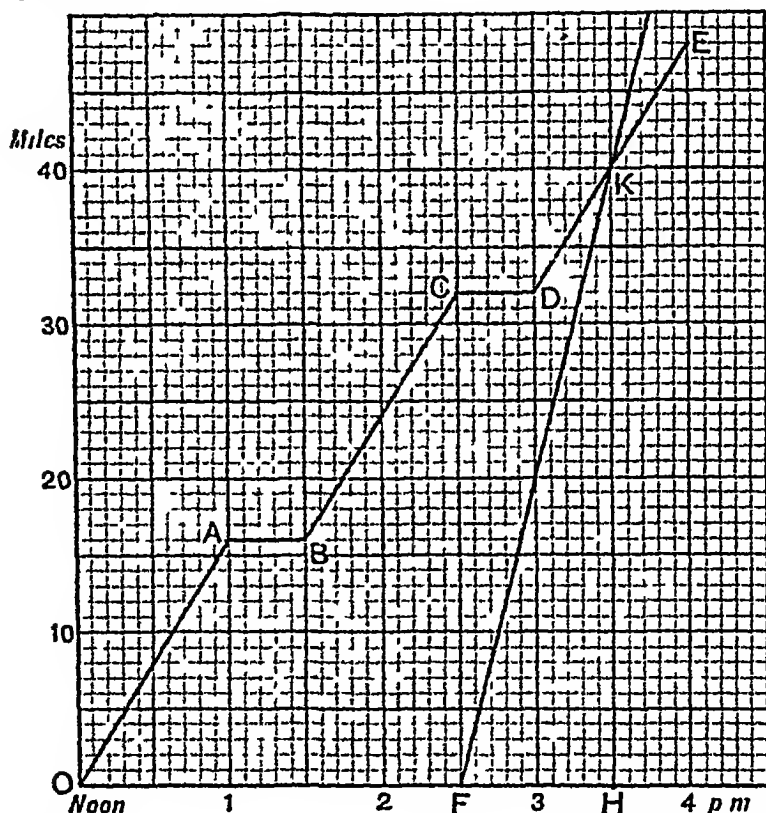

Measuring time horizontally, and miles vertically, as shown in the figure, OA is P's graph for the first hour

From 1 to 1 30 p m he stops,   AB is his graph for that time

In the same way BC is his graph from 1 30 to 2 30, CD from 2 30 to 3, DE from 3 to 4

Q starting at 2 30, FK is his graph, where FH = 1 hour and HK = 40 miles

From the figure we see that Q catches P up at 3 30 p m 40 miles from the start

[N B —Remember that during a stoppage time advances, whilst the distance from the start, i e vertical distance on paper, remains the same]

86 When we have more than two terms in the multiplier or multiplicand, the process is similar to that in simpler cases

Example 1 Multiply a^2+ab+b^2 by $a-b$

$$
\begin{array}{l}
a^2+ab+b^2 \\
\underline{a-b} \\
a^3+a^2b+ab^2 \\
\quad\ -a^2b-ab^2-b^3 \\
\overline{a^3\qquad\qquad\ -b^3}
\end{array}
$$

Example 2 Multiply $x^2-2xy+4y^2$ by $x^2+2xy+4y^2$

$$
\begin{array}{l}
x^2-2xy+\ \ 4y^2 \\
\underline{x^2+2xy+\ \ 4y^2} \\
x^4-2x^3y+4x^2y^2 \\
\quad\ 2x^3y-4x^2y^2+8xy^3 \\
\qquad\qquad 4x^2y^2-8xy^3+16y^4 \\
\overline{x^4\qquad\ +4x^2y^2\qquad\ +16y^4}
\end{array}
$$

Example 3 Multiply $4yz-3xy-2xz+x^2+y^2-z^2$ by $-y+2x-z$

Here we first arrange both multiplier and multiplicand in order of powers of x, and during the multiplication place like terms under one another

$$
\begin{array}{l}
x^2-3xy-2xz+y^2+4yz-z^2 \\
\underline{2x-y-z} \\
2x^3-6x^2y-4x^2z+2xy^2+\ 8xyz-2xz^2 \\
\quad\ -\ x^2y\qquad\quad+3xy^2+\ 2xyz\qquad\ -y^3-4y^2z+\ yz^2 \\
\qquad\ -\ x^2z\qquad\qquad\ +\ 3xyz+2xz^2\qquad\ -\ y^2z-4yz^2+z^3 \\
\overline{2x^3-7x^2y-5x^2z+5xy^2+13xyz\qquad\ -y^3-5y^2z-3yz^2+z^3}
\end{array}
$$

87 By multiplication it will be found that

$$(a+b)^3 = a^3 + 3a^2b + 3ab^2 + b^3,$$

$$(a-b)^3 = a^3 - 3a^2b + 3ab^2 - b^3$$

These results are useful and should be committed to memory.

88 *Analogy between Algebraical and Arithmetical methods of multiplication*

Multiply 213 by 23

$$\begin{array}{r} 213 \\ 23 \\ \hline 426 \\ 639 \\ \hline 4899 \end{array}$$

This is an abbreviated form of the following

$$\begin{array}{l} 2 \ 10^2 + 1 \ 10 + 3 \\ 2 \ 10 + 3 \\ \hline 4 \ 10^3 + 2 \ 10^2 + 6 \ 10 \\ \quad\quad 6 \ 10^2 + 3 \ 10 + 9 \\ \hline 4 \ 10^3 + 8 \ 10^2 + 9 \ 10 + 9 = 4899 \end{array}$$

If we now multiply $2x^2 + x + 3$ by $2x + 3$ we at once see the analogy between the two methods

$$\begin{array}{l} 2x^2 + \ x \ + 3 \\ 2x + 3 \\ \hline 4x^3 + 2x^2 + 6x \\ \quad\quad 6x^2 + 3x + 9 \\ \hline 4x^3 + 8x^2 + 9x + 9 \end{array}$$

89. Detached coefficients   The work in the above example is much shortened if we omit the powers of x, just as we omit powers of 10 in Arithmetic

The multiplication then stands thus

$$\begin{array}{l} 2x^2 + \ x \ + 3 \\ 2x + 3 \\ \hline 4 \ + 2 \ + 6 \\ \quad\quad 6 \ + 3 \ + 9 \\ \hline 4x^3 + 8x^2 + 9x + 9 \end{array}$$

inserting the requisite powers of x in the last line

Example 1   Multiply $4x^3 - 3x^2 - 11x + 2$ by $2x^2 - 5x + 9$

$$\begin{array}{l} 4x^3 - \ 3x^2 - 11x + \ 2 \\ 2x^2 - \ 5x + \ 9 \\ \hline 8 \ - 6 \ -22 \ + 4 \\ \quad -20 \ +15 \ +55 \ - 10 \\ \quad\quad\quad 36 \ -27 \ - 99 \ +18 \\ \hline 8x^5 - 26x^4 + 29x^3 + 32x^2 - 109x + 18 \end{array}$$

When powers of x are missing, 0 must be inserted as in Arithmetic

Example 2 Multiply $3x^3 - 7x + 9$ by $2x^2 - 3$

$$
\begin{array}{r}
3x^3 + 0x_1^2 - 7x + 9 \\
2x^2 - 0x - 3 \\
\hline
6 \quad +0 \quad -14 \quad +18 \\
-9 \quad -0 \quad +21 \quad -27 \\
\hline
6x^5 \qquad -23x^3 - 18x^2 + 21x - 27
\end{array}
$$

34 $2(x^2 + 2xy + y^2)$ and $3(x - y)^2$

35 $3(a^2 - ab + b^2)$ and $\frac{1}{3}(a + b)^2$

36 $a^2 + b^2 + c^2 - bc - ca - ab$ and $a + b - c$.

CHAPTER XVI

LONG DIVISION

90 **Example 1** Divide $8x^3 - 6x^2 - 3x - 18$ by $2x - 3$

$$
2x - 3 \,) \, 8x^3 - 6x^2 + 3x - 18 \, (\, 4x^2 + 3x + 6
$$
$$
\begin{array}{r}
\underline{8x^3 - 12x^2} \\
6x^2 + 3x \\
\underline{6x^2 - 9x} \\
12x - 18 \\
\underline{12x - 18}
\end{array}
$$

Before starting the work of division both divisor and dividend should be arranged in the same order (ascending or descending) of powers of one of the symbols used

Example 2 Divide $5x - 3 + x^3 + x^4 - 4x^2$ by $2x - 3 + x^2$

Arranging the expressions in descending powers of x,

$$
\begin{array}{l}
x^2+2x-3 \;)\; x^4+\;\;x^3-4x^2+5x-3 \;(\; x^2-x+1 \\
\underline{\;\;\;\;\;\;\;\; x^4+2x^3-3x^2} \\
\qquad\qquad -x^3-\;\;x^2+5x \\
\qquad\qquad \underline{-x^3-2x^2+3x} \\
\qquad\qquad\qquad\qquad x^2+2x-3 \\
\qquad\qquad\qquad\qquad \underline{x^2+2x-3}
\end{array}
$$

. (1)

(2)

(3)

. (4)

$\dfrac{x^4}{x^2}=x^2$, x^2 is the first term of the quotient

$$x^2(x^2+2x-3)=x^4+2x^3-3x^2,$$

and we thus obtain line (1) as in Arithmetic

Line (2) is obtained by subtraction, and by bringing down the term $+5x$

$$\dfrac{-x^3}{x^2}=-x,\qquad -x \text{ is the second term of the quotient}$$

$$-x(x^2+2x-3)=-x^3-2x^2+3x,$$

and we thus obtain line (3)

Line (4) is obtained in the same way as line (2)

$$\dfrac{x^2}{x^2}=1,\qquad 1 \text{ is the last term of the quotient}$$

There is no remainder, as we see by subtracting the last line

91 The analogy between the Algebraical and Arithmetical methods of division is at once seen if we compare the following

Remainder Theorem

94 *If* $ax^2 + bx + c$ *is divided by* $x - p$ *until the remainder is independent of* x, *that remainder will be* $ap^2 + bp + c$.

$$x - p \,)\, ax^2 + bx + c \,(\, ax + (ap + b)$$
$$\underline{ax^2 - apx}$$
$$(ap + b)x + c$$
$$\underline{(ap + b)x - (ap + b)p}$$
$$ap^2 + bp + c$$

This proves the theorem

It should be observed that this remainder may be obtained by substituting p for x in the dividend.

The above is true for all values of the symbols used, and hence

$$\text{when } 3x^2 - 4x + 5 \text{ is divided by } x - 2,$$
$$\text{the remainder} = 3 \times 2^2 - 4 \times 2 + 5$$
$$= 12 - 8 + 5 = 9$$

This of course can be tested by actual division

$$\text{Again when } 4x^2 - 7x + 9 \text{ is divided by } x + 5,$$
$$\text{the remainder} = 4(-5)^2 - 7(-5) + 9$$
$$= 100 + 35 + 9$$
$$= 144$$

95 *If $ax^3 + bx^2 + cx + d$ is divided by $x - p$ until the remainder is independent of x, that remainder will be*

$$ap^3 + bp^2 + cp + d$$

First method   Performing the actual division,

$$x - p \,) \; ax^3 + bx^2 + cx + d \; (\; ax^2 + (ap + b)x + (ap^2 + bp + c)$$
$$\underline{ax^3 - apx^2}$$
$$\overline{(ap + b)x^2 + cx}$$
$$\underline{(ap + b)x^2 - (ap + b)px}$$
$$\overline{(ap^2 + bp + c)x + d}$$
$$\underline{(ap^2 + bp + c)x - (ap^2 + bp + c)p}$$
$$ap^3 + bp^2 + cp + d$$

This proves the theorem

As before, the remainder may be obtained by substituting p for x in the dividend

$$\text{When } 4x^3 - 3x^2 + 7x - 9 \text{ is divided by } x - 11,$$
$$\text{the remainder} = 4 \times 11^3 - 3 \times 11^2 + 7 \times 11 - 9$$
$$= 5324 - 363 + 77 - 9$$
$$= 5029$$

$$\text{When } x^3 - 4x^2 + 6x - 4 \text{ is divided by } x - 2,$$
$$\text{the remainder} = 2^3 - 4 \times 2^2 + 6 \times 2 - 4$$
$$= 8 - 16 + 12 - 4$$
$$= 0$$

$x^3 - 4x^2 + 6x - 4$ is divisible by $x - 2$ without remainder

We thus have a ready means of testing whether any expression is exactly divisible by a given binomial e −

Second method   When $ax^3 + bx^2 + cx + d$ is divided by $x - p$ until the remainder is independent of x, let P denote the quotient, and R the remainder

Then $ax^3 + bx^2 + cx + d = (x - p) \times P + R$ (1)

[Just as in Arithmetic when we divide 57 by 9, $57 = 9 \times 6 + 3$]

Considering the equation (1), R is independent of x, by hypothesis   Also the equation is true whatever value we assign to x

Let $x = p$ Then the equation becomes

$ap^3 + bp^2 + cp + d = R$,   for $(x - p)P = (p - p)P = 0$

This proves the theorem

96   *For what value of p is $x^2 - (p + 2)x + 6$ divisible by $x - p$ without remainder ?*

When the division is performed the remainder, by the preceding articles,

$$= p^2 - (p + 2)p + 6$$
$$= p^2 - p^2 - 2p + 6$$
$$= -2p + 6$$

the reqd value of p is obtained by equating this remainder to zero, in which case $-2p + 6 = 0$,

$$2p = 6,$$
$$p = 3$$

97   *For what value of p is $x^3 - (p + 6)x^2 + (6p + c)x + d$ divisible by $x - p$ without remainder ?*

When the division is performed the remainder

$$= p^3 - (p + 6)p^2 + (6p + c)p + d$$
$$= p^3 - p^3 - 6p^2 + 6p^2 + cp + d$$
$$= cp + d$$

the reqd value of p is obtained from the equation

$$cp + d = 0,$$
$$cp = -d,$$
$$p = -\frac{d}{c}$$

CHAPTER XVIII

RESOLUTION INTO FACTORS

98   When an algebraic expression is expressed as a product of its factors, it is said to be resolved into factors, and the process of finding the factors is called resolution into factors

We have already dealt with some of the simpler forms of factorization, thus we have seen that $2x - 6 = 2(x-3)$

In other words the factors of $2x - 6$ are 2 and $(x-3)$

Example 1   Resolve $4a^2 - 3a$ into factors

a is common to both terms,
$$4a^2 - 3a = a(4a-3),$$
or, the factors of $4a^2 - 3a$ are a and $(4a-3)$

Example 2 $6x^3 - 7x^2 - 2x = x(6x^2 - 7x - 2)$

Example 3 $3a^2bc - 5ab^2c + 4abc^2 = abc(3a - 5b + 4c)$

Example 4 $15x^2y^3 - 5xy^4 - 20x^4y^2 = 5xy^2(3xy - y^2 - 4x^3)$

N B —The above results should be checked by removing the brackets

Examples   XVIII a

1 $ax + ab$	2 $ax - a^2$	3 $x^2 - 3ax$
4. $x^3 - 5ax^2$	5 $ax^2 - a^2x + a^3$	6 $3a^2 - 3ab$
7 $5x^3 - 15x^2y$	8 $x^2 - xy$	9 $21 - 56x$
10 $25x^2 - 20xy$	11 $ax - bx + cx$	12 $-2x^3 + 4x$
13 $-ay + by + cy$	14. $p^2x^2 - apxy + pbxy$	
15 $76a^2x^3 - 57a^3x^2$	16 $3p^2x^2 - 9px + 12$	
17 $x^2yz + xy^2z - xyz^2$	18 $7ab - 7bc - 21bx$	
19 $14x^3 - 7x^2y + 56xy^2$,	20 $36x^2yz - 54xy^2z + 48xyz^2 - 18x^2y^2z^2$	

TRINOMIAL EXPRESSIONS

99　An algebraic expression of three terms is called a trinomial
Examine the four multiplications given below

$$
\begin{array}{l}
x+2 \\
x+3 \\
\hline
x^2+2x \\
\quad +3x+6 \\
\hline
x^2+5x+6
\end{array}
$$

$$(x+2)(x+3)$$
$$=x^2+5x+6 \quad \text{(i)}$$

$$
\begin{array}{l}
x-2 \\
x-3 \\
\hline
x^2-2x \\
\quad -3x+6 \\
\hline
x^2-5x+6
\end{array}
$$

$$(x-2)(x-3)$$
$$=x^2-5x+6 \quad \text{(ii)}$$

$$
\begin{array}{l}
x+2 \\
x-3 \\
\hline
x^2+2x \\
\quad -3x-6 \\
\hline
x^2-\;x-6
\end{array}
$$

$$(x+2)(x-3)$$
$$=x^2-x-6 \quad \text{(iii)}$$

$$
\begin{array}{l}
x-2 \\
x+3 \\
\hline
x^2-2x \\
\quad +3x-6 \\
\hline
x^2+\;x-6
\end{array}
$$

$$(x-2)(x+3)$$
$$=x^2+x-6 \quad \text{(iv)}$$

The results are different forms of the expression

$$x^2+px+q$$

In each case we notice in the product that

(1) the coefficient of x is the algebraic sum of the second terms of the factors

(2) the third term is the product of the second terms of the factors

In　(i) $2+3=5$,　$2\times3=6$

In　(ii)　$-2-3=-5$,　$(-2)(-3)=6$

In (iii) $2-3=-1$,　$(2)(-3)=-6$

In (iv)　$-2+3=1$,　$(-2)(3)=-6$

Reversing the process, in order to find the factors of an expression of the form x^2+px+q, we must seek two numbers whose algebraic sum is p and whose product is q

Examples

$x^2+7x+12=(x+4)(x+3)$, for $4+3=7$ and $4\times3=12$

$x^2-7x+12=(x-4)(x-3)$, for $-4-3=-7$ and $(-3)(-4)=12$

$(x^2-4x-12)=(x-6)(x+2)$, for $-6+2=-4$ and $(-6)(2)=-12$

$(x^2+4x-12)=(x+6)(x-2)$, for $6-2=4$ and $(6)(-2)=-12$

100 In more general form the above results may be expressed thus

$$x^2 + (a+b)x + ab = (x+a)(x+b),$$
$$x^2 - (a+b)x + ab = (x-a)(x-b),$$
$$x^2 + (a-b)x - ab = (x+a)(x-b),$$
$$x^2 - (a-b)x - ab = (x-a)(x+b)$$

All the above can of course be checked by multiplying the factors

We also see that

$$abx^2 + (a+b)x + 1 = (ax+1)(bx+1),$$
$$abx^2 - (a+b)x + 1 = (ax-1)(bx-1),$$
$$abx^2 + (a-b)x - 1 = (ax-1)(bx+1),$$
$$abx^2 - (a-b)x - 1 = (ax+1)(bx-1)$$

Thus
$$3x^2 + 4x + 1 = (3x+1)(x+1),$$
$$10x^2 - 3x - 1 = (5x+1)(2x-1),$$
$$10x^2 + 3x - 1 = (5x-1)(2x+1)$$

Also
$$x^2 - 11xy + 10y^2 = (x-10y)(x-y),$$
$$x^2 - 4xy - 21y^2 = (x-7y)(x+3y)$$

101 An expression of four terms can often be factorized $\mathfrak{l}$ grouping the terms in pairs

Examples
$$ax-bx+ay-by$$
$$=(a-b)x+(a-b)y$$
$$=(a-b)(x+y) \text{ [just as } cx+cy=c(x+y)]$$
$$3ax-2by-3bx+2ay$$
$$=(3ax-3bx)+(2ay-2by)$$
$$=3x(a-b)+2y(a-b)$$
$$=(a-b)(3x+2y)$$

We might deal with $x^2-(a+b)x+ab$ in this way
$$x^2-(a+b)x+ab=x^2-ax-bx+ab$$
$$=x(x-a)-b(x-a)$$
$$=(x-a)(x-b)$$
$$x^3-ax^2+a^2x-a^3=(x^3-ax^2)+(a^2x-a^3)$$

106 Factorization of trinomial expressions when the co-efficient of the highest term is not unity

This can often be done by inspection, but if the factors are not readily seen, the method described in the next article should be employed

$$10x^2 + 29x - 21 = (5x - 3)(2x + 7)$$

Arrange the factors thus

$$\begin{matrix} 5x - 3 \\ \times \\ 2x + 7 \end{matrix}$$

Firstly We see that the *first* term of the product is the product of the *first* terms of the factors, and the *last* term of the product is the product of the *second* terms of the factors

Thus if $6x^2 + 11x - 35$ has factors,

their first terms must be $6x$ and x, or $3x$ and $2x$

Also, their second terms must be 35 and 1, or 5 and 7, with proper signs prefixed

Secondly We see that the coefficient of x is formed by the products $5x \times 7$ and $2x \times (-3)$ [Notice the crossed lines ($\times$) above]

We also notice that if the *last* term of the product is *positive,* the *second* terms of the factors have the same sign   if the *last* term of the product is *negative,* the *second* terms of the factors have different signs

Let us take a few cases

Example   Factorize $3x^2 - 17x + 10$
The *first* terms of the factors must be $3x$ and x
The *second*   10 and 1, or 2 and 5
                        are of the same sign, and *negative*
We therefore have to choose from the following

$$\left.\begin{matrix} x - 10 \\ \times \\ 3x - 1 \end{matrix}\right\}$$ the coeff of x would be $-(1 + 3 \times 10)$

$$\left.\begin{matrix} x - 1 \\ \times \\ 3x - 10 \end{matrix}\right\}$$ $-(10 + 3)$

$$\left.\begin{matrix} 3x - 5 \\ \times \\ x - 2 \end{matrix}\right\}$$ $-(3 \times 2 + 5)$

$$\left.\begin{matrix} 3x - 2 \\ \times \\ x - 5 \end{matrix}\right\}$$ $-(3 \times 5 + 2)$

The last case is therefore the only possible one, and we see that the
factors are $3x - 2$ and $x - 5$

After a little practice it will easily be seen which cases may be rejected

Example   Factorize $7x^2 + 32x - 15$
The *first* terms of the factors must be $7x$ and x
The *second*   have different signs

$$\left.\begin{array}{c}7x+15\\ \times\\ x-1\end{array}\right\}\quad \text{coeft of } x \text{ would be } -7\times1+15\times1=8$$

$$\left.\begin{array}{c}7x-15\\ \times\\ x+1\end{array}\right\}\qquad 7\times1-15\times1=-8$$

$$\left.\begin{array}{c}7x-1\\ \times\\ x+15\end{array}\right\}\qquad 7\times15-1=104$$

$$\left.\begin{array}{c}7x+1\\ \times\\ x-15\end{array}\right\}\qquad -7\times15+1=-104$$

$$\left.\begin{array}{c}7x+5\\ \times\\ x-3\end{array}\right\}\qquad -7\times3+5=-16$$

$$\left.\begin{array}{c}7x-5\\ \times\\ x+3\end{array}\right\}\qquad 7\times3-5=16$$

$$\left.\begin{array}{c}7x+3\\ \times\\ x-5\end{array}\right\}\qquad -7\times5+3=-32$$

$$\left.\begin{array}{c}7x-3\\ \times\\ x+5\end{array}\right\}\qquad 7\times5-3=32$$

$7x-3$ and $x+5$ are the reqd factors.

Example   Factorize $3x^2 - 8x - 3$
    3 is *not* a factor of each term $3x-3$ cannot be a factor
                    the factors must be
            $3x-1$ and $x+3$, or $3x+1$ and $x-3$
The second pair are the factors, for $-3\times3+1=-8$

107 When the factors cannot readily be seen by inspection the following method is recommended.

Example 1   Find the factors of $2x^2 - 5x + 2$
$$2x^2 - 5x + 2 = \tfrac{1}{2}\{(2x)^2 - 5(2x) + 4\}$$
(This is the same as multiplying by $\tfrac{2}{2}$)
(Writing y instead of $2x$) $\quad = \tfrac{1}{2}[y^2 - 5y + 4]$
$$= \tfrac{1}{2}(y-4)(y-1)$$
$$= \tfrac{1}{2}(2x-4)(2x-1)$$
$$= (x-2)(2x-1)$$

Example 2 Factorize $12x^2 - x - 20$

$$12x^2 - x - 20 = \tfrac{1}{12}[(12x)^2 - (12x) - 240]$$

(Writing y instead of $12x$)
$$= \tfrac{1}{12}(y^2 - y - 240)$$
$$= \tfrac{1}{12}(y - 16)(y + 15)$$
$$= \tfrac{1}{12}(12x - 16)(12x + 15)$$
$$= \left(\frac{12x - 16}{4}\right)\left(\frac{12x + 15}{3}\right)$$
$$= (3x - 4)(4x + 5)$$

Example 3 Factorize $28x^2 + xy - 45y^2$

$$28x^2 + xy - 45y^2 = \tfrac{1}{28}[(28x)^2 + (28x)y - 28 \times 45y^2]$$

(Writing a instead of $28x$)
$$= \tfrac{1}{28}(a^2 + ay - 28 \times 45y^2)$$

We now have to find two numbers whose product is -28×45, and whose algebraic sum is 1   This can easily be done if we put the product -28×45 into its prime factors

$$-28 \times 45 = -2 \times 2 \times 7 \times 5 \times 3 \times 3$$
$$-7 \times 5 + 2 \times 2 \times 3 \times 3 = -35 + 36 = 1,$$

the given expression $= \tfrac{1}{28}(a + 36y)(a - 35y)$
$$= \tfrac{1}{28}(28x + 36y)(28x - 35y)$$
$$= (7x + 9y)(4x - 5y)$$

109 The Remainder Theorem (Art 95) is often useful for purposes of factorization

Factorize the expression x^3+4x^2+x-6

When this expression is divided by $x-1$, the remainder
$$=1+4+1-6=0, \tag{1}$$
i e the expression is divisible by $x-1$ without remainder, in other words $x-1$ is a factor

Knowing this we write the expression thus
$$x^3-1+4(x^2-1)+x-1$$
$$=(x-1)(x^2+x+1)+4(x-1)(x+1)+x-1$$
$$=(x-1)(x^2+x+1+4x+4+1)$$
$$=(x-1)(x^2+5x+6)$$
$$=(x-1)(x+2)(x+3)$$

From the above [see (1)] we observe that in any algebraical expression where x is the only symbol used, if the algebraical sum of the numerical coefficients is zero, $x-1$ is a factor of the expression

Example   Factorize the expression $6x^3+13x^2+2x-5$

When we divide by $x+1$, the remainder is
$$-6+13-2-5=0, \tag{1}$$
$x+1$ is a factor of the expression

Knowing this we write the expression in the form
$$6(x^3+1)+13(x^2-1)+2(x+1)$$
$$=6(x+1)(x^2-x+1)+13(x+1)(x-1)+2(x+1)$$
$$=(x+1)(6x^2-6x+6+13x-13+2)$$
$$=(x+1)(6x^2+7x-5)$$
$$=(x+1)(3x+5)(2x-1)$$

Hence, comparing (1) with the given expression, we observe that in any algebraical expression where x is the only symbol used, if the algebraical sum of the coefficients of the even powers of x

is equal to that of the odd powers of x, x + 1 is a factor of the expression.

110 *Prove that* $(a-b)$, $(b-c)$, $(c-a)$ *are factors of the expression*
$$a^3(b-c)+b^3(c-a)+c^3(a-b)$$

When we arrange the given expression in descending powers of a and divide by $a-b$, the remainder is equal to the value of the expression obtained by putting $a=b$ (Remainder Theorem)

This remainder $=b^3(b-c)+b^3(c-b)=0$,

$a-b$ is a factor of the given expression

In the same way we may prove that $b-c$ and $c-a$ are factors of the same expression

111 Miscellaneous factors

Example 1   Factorize the expression x^4-a^4
$$x^4-a^4=(x^2+a^2)(x^2-a^2)$$
$$=(x^2+a^2)(x+a)(x-a)$$

Example 2   Factorize the expression x^6-a^6
$$x^6-a^6=(x^3+a^3)(x^3-a^3)$$
$$=(x+a)(x^2-ax+a^2)(x-a)(x^2+ax+a^2)$$

In a case of this kind it is advisable to consider the expression as the difference of two squares *first,* as above

Example 3   Resolve into factors $3x^4-3x^3y-18x^2y^2$
$$3x^4-3x^3y-18x^2y^2=3x^2(x^2-xy-6y^2)$$
$$=3x^2(x-3y)(x+2y)$$

Example 4   Resolve $(a+b)^3-1$ into factors
$$(a+b)^3-1=[(a+b)-1][(a+b)^2+(a+b)+1]$$
$$=(a+b-1)(a^2+2ab+b^2+a+b+1)$$

Example 5   Resolve $32(x+y)^3-2x-2y$ into factors
$$32(x+y)^3-2x-2y=32(x+y)^3-2(x+y)$$
$$=2(x+y)[16(x+y)^2-1]$$
$$=2(x+y)[4(x+y)+1][4(x+y)-1]$$
$$=2(x+y)(4x+4y+1)(4x+4y-1)$$

Example 6   Resolve $9x^2-49y^2-9x+21y$ into factors
$$9x^2-49y^2-9x+21y=(3x+7y)(3x-7y)-3(3x-7y)$$
$$=(3x-7y)(3x+7y-3)$$

CHAPTER XIX.

HIGHEST COMMON FACTOR

112 When a term is the product of several letters, each of the letters is called a dimension of the product   Also the number of letters, when expressed without indices, denotes the degree of the product

$a^3bc = a\ a\ a\ b\ c$,   and is therefore of five dimensions Numerical coefficients are considered as of no degree

$9x^2yz$, and $13x^2yz$ are therefore of the same degree, the fourth

The highest common factor (H C F) or highest common divisor (H C D) of two or more integral algebraic expressions is the integral expression of the highest degree which will exactly divide each of them.

Consider the expressions $27a^2b^3c$, $15a^3b^5c^4$ 3 is the H C F of the numerical coefficients 27 and 15

The highest power of a which will divide both expressions is a^2

$$b \qquad\qquad\qquad\qquad b^3$$
$$c \qquad\qquad\qquad\qquad c$$

the H C F of the two expressions is $3a^2b^3c$

Example   Find the H C F of $15a^3b^4c^2$, $60a^2b^3$, $25a^4b^2c^2$

The H C.F of 15, 60, 25 is 5
The highest power of a which divides all the expressions is a^2

$$b \qquad\qquad\qquad\qquad b^2$$

No power of c divides all three expressions
    the reqd H C.F $=5a^2b^2$

Examples   XIX a

1 $5a^2b$, $10ab^2$	2 x^2y^3, x^3y^2	3 abc, $3a^2b$
4. $6xy^2z$, $8x^3y^2z^2$	5 $9a^3b^2c^2$, $15a^2bc^4$	6 $9a^2x^4$, $21b^2x^3$
7 $6x^2y$, $3xy^2$, $9x^2y^2$	8 x^2y, y^2z, zy^2	9 $3a^2c^2$, $27a^4c^4$, $18a^3c^2$
10 $26x^3y^2$, $13x^2z^3$, $39x^4y^2z^2$	11 $35x^2b^4c^2d^2$, $20x^5c^2d^4$, $45a^7b^2d$, $10a^7b^4cd^7$	
12 $3abc^2$, $5a^2bc$, $7abc^2$, $9abcd$		

113 In *compound expressions* the H C F can be determined by inspection as soon as the expressions are resolved into their simplest factors

Example 1. Find the H C.F of
$$a^2bx + ab^2c \text{ and } a^2b - b^3$$
$$a^2bx + ab^2x = abx(a+b),$$
$$a^2b - b^3 = b(a^2 - b^2) = b(a+b)(a-b)$$
By inspection the reqd H C F is $b(a+b)$

Example 2   Find the H C F of $x^2 - 17x + 60$ and $x^2 + 7x - 60$
$$x^2 - 17x + 60 = (x-12)(x-5),$$
$$x^2 + 7x - 60 = (x+12)(x-5)$$
the reqd H C F is $x - 5$

Example 3   Find the H C F of x^2-4, x^2+3x+2, x^2+x-2

$$x^2-4=(x-2)(x+2),$$
$$x^2+3x+2=(x+1)(x+2),$$
$$x^2+x-2=(x-1)(x+2)$$

$x+2$ is the H C F reqd

Example 4   Find the H C F of $x^3-ax^2+a^2x-a^3$ and $x^3-ax^2-a^2x+a^3$

$$x^3-ax^2+a^2x-a^3=x^2(x-a)+a^2(x-a)=(x-a)(x^2+a^2),$$
$$x^3-ax^2-a^2x+a^3=x^2(x-a)-a^2(x-a)=(x-a)(x^2-a^2)$$
$$=(x+a)(x-a)^2$$

the reqd H C F is $x-a$

114. When compound expressions cannot readily be factorized we find their H C F by a method analogous to the Arithmetical method

Before attempting any such, the student must grasp the principle underlying the Arithmetical method

Let us find the H C F of 782 and 5451

$$782) 5451 (6$$
$$\underline{4692}$$
$$759) 782 (1$$
$$\underline{759}$$
$$23) 759 (33$$
$$\underline{69}$$
$$\overline{69}$$
$$\underline{69}$$

23 is the reqd H C F

This method depends upon the fact that if any two numbers have a common factor, the remainder, when one is divided by the other, has the same factor

Thus in the above,

> any factor common to 782 and 5451 is a factor of 759
> 759 and 782　　　　　　　　　　 23

This principle, a rigid proof of which will be given later, being true for Arithmetical numbers must also be true in Algebra, since the symbols stand for numbers

Let us now apply it to some examples

Example 1　Find the H C F of $x^3 + 6x^2 - 8x - 7$ and $x^3 + 8x^2 + 10x + 21$

$$x^3 + 6x^2 - 8x - 7) x^3 + 8x^2 + 10x + 21 (1$$
$$\underline{x^3 + 6x^2 - 8x - 7}$$
(a)　$\underline{2) 2x^2 + 18x + 28}) x^3 + 6x^2 - 8x - 7 (x - 3$
$$x^2 + 9x + 14 \quad \underline{x^3 + 9x^2 + 14x}$$
$$-3x^2 - 22x - 7$$
$$\underline{-3x^2 - 27x - 42}$$
(b)　$\underline{5) 5x + 35} (x^2 + 9x + 14) x + 2$
$$x + 7 \quad \underline{x^2 + 7x}$$
$$2x + 14$$
$$\underline{2x + 14}$$

$x + 7$ is the reqd H C F

(a) Here we see that 2 is a factor of $2x^2 + 18x + 28$, *but not a factor of* $x^3 + 6x^2 - 8x - 7$　we therefore reject it

(b) We see that 5 is a factor of $5x + 35$, *but not a factor of* $x^2 + 9x + 14$ we therefore reject it

The work will be considerably simplified if factors not common to both divisor and dividend are rejected in this way

Time will be saved if the work is arranged as below

```
 x | x³+6x²−  8x−  7    |   x³+8x²+10x+21 | 1
   | x³+9x²+14          |   x³+6x²−  8x−  7
   |                    |   ─────────────
−3 | −3x²−22x−  7       |   2) 2x²+18x+28
   | −3x²−27x−42        |   ─────────────
   | ──────────────     |      x²+  9x+14 | x          (c)
   | 5 ) 5x+35          |      x²+  7x
   | ──────────────     |      ──────────
   |        x+ 7        |         2x+14   | 2
   |                    |         2x+14
```

At the stage (c) we might have shortened the work thus   The factors of $x^2+9x+14$ are $x+2$ and $x+7$ $x+2$ is evidently not a divisor of the given expressions

Dividing x^3+6x^2-8x-7 by $x+7$ we find that $x+7$ is the H.C F

When the given expressions have factors common to every term, these should be removed first, remembering that they themselves may have a common factor

Example 2   Find the H C F of
$$36x^4-78x^3+18x^2+12x \quad \text{and} \quad 90x^4-207x^3+63x^2+36x$$
$$36x^4- 78x^3+18x^2+12x=6x(6x^3-13x^2+3x+2)$$
$$90x^4-207x^3+63x^2+36x=9x(10x^3-23x^2+7x+4)$$

$3x$ is the H C F of $6x$ and $9x$

We now proceed to find the H C F of the remaining factors

```
3x | 6x³−13x²+3x+2    |   10x³−23x²+7x+4 | 2
   | 6x³−  9x²−3x     |   12x³−26x²+6x+4
−2 | ──────────────  |   −x) −2x³+ 3x²+ x
   | −  4x²+6x+2      |      2x³−  3x − 1
   | −  4x²+6x+2
```

the reqd. H C F is $3x(2x^2-3x-1)$

Example 3   Find the H C F of
$$6x^3-19x^2+11x+6 \quad \text{and} \quad 10x^3-19x^2+2x+6$$

```
(c) |  6x³−19x²+11x+  6    |   10x³−19x²+  2x+6 | 1
    |               2     |    6x³−19x²+  11x+6
 3x | 12x³−38x²+22x+12     |    ───────────────      (a)
    | 12x³       −27x      |   x ) 4x³      − 9x | (d)
 −9 | ──────────────      |      4x²        − 9
(b) | −38x²+49x+12         |      4x²−98x +1³8
    | −36x²      +81       |      49) 98x −147
 −1)| − 2x²+49x−69         |         2x −  3    | 2
    | 2x²−49x+69
  x | 2x²−  3x
−23 |      −46x+69
    |      −46x+69
```

The reqd H C F is $2x-3$

N B —It is not necessary that the first term of the divisor should go an exact number of times into the first term of the dividend   See (*a*) and (*b*)

It is, however, sometimes convenient, as at (*c*), to introduce a factor

At (*d*) we reject the factor *x*, which is not a factor of either of the given expressions

115 If A and B represent any integral algebraical expression, then if A and B have a common factor, their sum or difference has the same factor

Let *p* be the common factor of A and B, and C and D the quotients when we divide them by *p*

$$\text{Then } A=pC, \text{ and } B=pD$$

$$A+B=p(C+D), \text{ } i\,e \text{ } p \text{ is a factor of } A+B$$

In the same way $A-B=p(C-D)$,   *p* $A-B$

Further if A and B have a common factor *p*, *p* is also a factor of *m*A + *n*B and *m*A − *n*B, where *m*A and *n*B are any multiples of A and B

Let C and D be the quotients when we divide A and B by *p*, so that $A=pC, \text{ and } B=pD$

$$mA+nB=mpC+npD$$
$$=p(mC+nD),$$
$$p \text{ is a factor of } mA+nB$$

In the same way, $mA-nB=p(mC-nD),$
$$p \text{ is a factor of } mA-nB$$

This can often be employed to shorten the work of finding a H C F

Find the H C F of

$$5x^3+16x^2+23x-5148 \text{ and } 3x^3+48x^2-103x-5148$$

The difference of the two expressions

$$=2x^3-32x^2+126x$$
$$=2x(x^2-16x+63)$$
$$=2x(x-7)(x-9)$$

Now 2*x* is not a common factor, nor is *x* − 7, for 7 will not divide exactly into 5148

$x-9$ must be the H C F if there is one

20   $3x^3 + 17x^2 - 62x + 14, \quad 7x^3 + 52x^2 - 46x + 8$

REDUCTION OF FRACTIONS TO LOWEST TERMS

116 We shall assume throughout that as the symbols stan for numerical quantities, the ordinary Arithmetical rules concerning Vulgar Fractions apply to Algebra, leaving the proofs of those rules to a later stage

In Arithmetic $\dfrac{6}{8} = \dfrac{3 \times 2}{4 \times 2} = \dfrac{3}{4}$

So in Algebra $\dfrac{ma}{mb} = \dfrac{a}{b}$

$$\frac{abc^2}{b^2c} = \frac{ac \times bc}{b \times bc} = \frac{ac}{b}$$

$$\frac{ax - bx}{abx} = \frac{(a - b) \times x}{ab \times x} = \frac{a - b}{ab}$$

$$\frac{4a^2 - 6ab}{6a^2 - 4ab} = \frac{2a(2a - 3b)}{2a(3a - 2b)} = \frac{2a - 3b}{3a - 2b}$$

$$\frac{x^2 - 5x + 6}{x^2 - 4x + 4} = \frac{(x - 2)(x - 3)}{(x - 2)^2} = \frac{(x - 2)(x - 3)}{(x - 2)(x - 2)} = \frac{x - 3}{x - 2}$$

117. A fraction is reduced to its lowest terms by dividing its numerator and denominator by their H.C F

The H C F should always be found by factorization, when possible

Reduce $\dfrac{3x^2 + 2x - 1}{x^3 + x^2 - x - 1}$ *to its lowest terms*

The given expression $= \dfrac{(3x - 1)(x + 1)}{x^2(x + 1) - (x + 1)}$

$$= \frac{(3x - 1)(x + 1)}{(x^2 - 1)(x + 1)}$$

$$= \frac{3x - 1}{x^2 - 1} \text{ in its lowest terms}$$

Reduce $\dfrac{a^3 - 7a^2 + 16a - 12}{3a^3 - 14a^2 + 16a}$ *to its lowest terms*

The denominator $= a(3a^2 - 14a + 16) = a(3a - 8)(a - 2)$

Hence it is evident that if the numerator and denominator have a common factor, it is $a - 2$

Acting on this knowledge, we write the numerator to show $a - 2$ as a factor, thus

$$(a^3 - 2a^2) - (5a^2 - 10a) + 6a - 12$$
$$= a^2(a - 2) - 5a(a - 2) + 6(a - 2)$$
$$= (a^2 - 5a + 6)(a - 2)$$
$$= (a - 2)(a - 3)(a - 2),$$

the given expression $= \dfrac{(a - 2)(a - 3)(a - 2)}{a(3a - 8)(a - 2)} = \dfrac{(a - 2)(a - 3)}{a(3a - 8)}$

LOWEST COMMON MULTIPLE

119 The lowest common multiple (L C M) of two or more integral algebraic expressions is the integral expression of the lowest degree which is exactly divisible by each of them

The L C M of a^3b^2 and ab^3 is a^3b^3

$\qquad\qquad a^2, a^7, a^2, a$ is a^7

$\qquad\qquad 12a^3$ and $18a^2$ is $36a^3$, for 36 is the L C M of 12 and 18, and a^3 is the L C M of a^3 and a^2

Example 1 Find the L C M of $21a^6b^3c$, $7a^3b^2c^4$, and $2a^2b^6c^3$

The L C M of 21, 7, and 2 is 42

The L C M of a^6b^3c, $a^3b^3c^4$, $a^2b^5c^3$

must contain a^6 or it would not be divisible by the first expression,
it $\qquad\qquad b^5 \qquad\qquad$ ` $\qquad\qquad\qquad$ third
and $\qquad\qquad c^4 \qquad\qquad\qquad\qquad\qquad\qquad\qquad$ second

$\qquad\qquad 42a^6b^5c^4$ is the reqd L C M

12 ay^2, az^2, a^2y, a^2z $\qquad\qquad$ 13 $a, 2a, 3a, 4a, 5a$

16 $8x^3y^4z^5, 5x^5y^2z^5, 12x^2y^4z^6, 16x^5y^4z^2$

120 The L C M of *compound expressions* can be determined by inspection when the expressions have been resolved into their simplest factors

Example 1   Find the L.C.M of $a^3b - a^2bx$ and $ab^2c - b^2cx$

$$a^3b - a^2bx = a^2b\,(a - x),$$
$$ab^2c - b^2cx = b^2c\,(a - x)$$

Thus we see that the reqd L C M is $a^2b^2c\,(a - x)$

Example 2   Find the L.C M of $x^2 - 5x + 6$ and $x^2 + 2x - 8$

$$x^2 - 5x + 6 = (x - 2)(x - 3),$$
$$x^2 + 2x - 8 = (x - 2)(x + 4),$$
$$(x - 2)(x - 3)(x + 4) \text{ is the reqd L C M}$$

Example 3 $4a^4b^2c + 4a^3b^2cx$, $6a^3bc^2 - 6a^2bc^2x$, and $3a^2b^3c - 3b^3cx^2$

$$4a^4b^2c + 4a^3b^2cx = 4a^3b^2c\,(a + x),$$
$$6a^3bc^2 - 6a^2bc^2x = 6a^2bc^2\,(a - x),$$
$$3a^2b^3c - 3b^3ca^2 = 3b^3c\,(a^2 - x^2) = 3b^3c\,(a - x)(a + x)$$

CHAPTER XXI

ADDITION AND SUBTRACTION OF FRACTIONS

121 We have already seen that, just as in Arithmetic

$$\frac{3}{7}+\frac{5}{7}=\frac{3+5}{7},$$

so in Algebra

$$\frac{x}{a}+\frac{y}{a}=\frac{x+y}{a},$$

and

$$\frac{x}{a}-\frac{y}{a}=\frac{x-y}{a}$$

When in Arithmetic we wish to add or subtract fractions which have different denominators, the plan is to reduce all the fractions to *equivalent fractions having the same denominator*

We adopt the same plan in Algebra

Example 1 $\dfrac{x-3}{4}-\dfrac{x-2}{6}=\dfrac{3(x-3)}{3\times4}-\dfrac{2(x-2)}{2\times6}$

[12 is the L C M of the denominators 4 and 6   We therefore multiply numerator and denominator in the first fraction by 3, and in the second by 2]

$$=\frac{3(x-3)-2(x-2)}{12}=\frac{3x-9-2x+4}{12}\text{ (removing brackets)}$$

$$=\frac{x-5}{12}\text{ (collecting like terms)}$$

Example 2   Simplify $\dfrac{x+3}{3x}-\dfrac{4x-3}{4x^2}+\dfrac{5}{2x^3}$

The given expression $=\dfrac{4x^2(x+3)}{4x^2\times3x}-\dfrac{3x(4x-3)}{3x\times4x^2}+\dfrac{6\times5}{6\times2x^3}$

(the L C M of $3x$, $4x^2$, $2x^3$ is $12x^3$)

$$=\frac{4x^3+12x^2-12x^2+9x+30}{12x^3}$$

$$=\frac{4x^3+9x+30}{12x^3}$$

Examples   XXI a

Simplify the following expressions

1 $\dfrac{1}{x}+\dfrac{1}{3x}+\dfrac{1}{2x}$ 2 $\dfrac{a}{x}+\dfrac{a}{3x}-\dfrac{a}{2x}$ 3 $\dfrac{1}{a}+\dfrac{1}{b}+\dfrac{1}{c}$

4 $\dfrac{1}{ax}+\dfrac{1}{bx}-\dfrac{1}{cx}$ 5 $\dfrac{a}{bc}+\dfrac{b}{ac}+\dfrac{c}{ab}$ 6 $\dfrac{x-3}{3}-\dfrac{x-4}{4}$

7 $\dfrac{x}{6}-\dfrac{x+1}{7}$ 8 $\dfrac{2x-1}{3}-\dfrac{4x-8}{6}$ 9 $\dfrac{x-a}{a}-\dfrac{x-b}{b}$

10 $\dfrac{3x-y}{xy}-\dfrac{3z-2y}{yz}$ **11** $\dfrac{x-3}{3x}-\dfrac{x-5}{5x}$ **12.** $\dfrac{q+3r}{3qr}-\dfrac{2p-q}{2pq}$

13 $\dfrac{x+1}{2}+\dfrac{x+2}{3}+\dfrac{x-4}{4}$ **14.** $\dfrac{x+y}{5}-\dfrac{2x-7y}{10}+\dfrac{x-3y}{3}$

15 $\dfrac{a-b}{b}-\dfrac{a+b}{a}+\dfrac{a^2+4ab+2b^2}{2ab}$ **16** $\dfrac{x-y}{xy}+\dfrac{y-z}{yz}+\dfrac{z-x}{zx}$

17 $\dfrac{2c-a}{3c}-\dfrac{a-b}{2a}+\dfrac{3b}{4a}$ **18** $\dfrac{x-y}{x}+\dfrac{x^3+y^3}{xy^2}-\dfrac{x^2+y^2}{x^2}.$

19 $\dfrac{3b+4a}{2ab}+\dfrac{b-6c}{3bc}-\dfrac{a+6c}{4ac}$ **20** $\dfrac{2x+1}{3x}-\dfrac{3x+2}{5x}+\dfrac{1}{7}$

21 $\dfrac{a^2-b^2}{a^2b^2}-\dfrac{c^2-b^2}{b^2c^2}+\dfrac{c^2-a^2}{a^2c^2}$ **22** $\dfrac{3x-6y}{3}-\dfrac{21x-14y}{7}+\dfrac{38x-57y}{19}$

122 Note carefully the truth of the following statements

$$\frac{1}{2-x}=\frac{-1}{x-2}=-\frac{1}{x-2}$$

This is obtained by multiplying numerator and denominator by -1

In the same way $$\frac{a-b}{c-d}=\frac{b-a}{d-c},$$

and again $$\frac{4x-3y}{y-x}=-\frac{4x-3y}{x-y}$$

Example 1 $$\frac{7a}{a-b}-\frac{3a-2b}{b-a}=\frac{7a}{a-b}+\frac{3a-2b}{a-b}$$
$$=\frac{7a+3a-2b}{a-b}=\frac{10a-2b}{a-b}$$

Example 2   Simplify $\dfrac{x+3y}{x+y}-\dfrac{x-6y}{x+2y}$

The ʟ ᴄ ᴍ of $x+y$ and $x+2y$ is $(x+y)(x+2y)$

Multiplying numerator and denominator in the first fraction by $x+2y$,

second $x+y$,

the given expression $=\dfrac{(x+2y)(x+3y)}{(x+2y)(x+y)}-\dfrac{(x+y)(x-6y)}{(x+2y)(x+y)}$ (a)

$$=\frac{(x+2y)(x+3y)-(x+y)(x-6y)}{(x+2y)(x+y)}$$

$$=\frac{x^2+5xy+6y^2-(x^2-5xy-6y^2)}{(x+2y)(x+y)}$$

$$=\frac{x^2+5xy+6y^2-x^2+5xy+6y^2}{(x+2y)(x+y)}$$ (b)

$$=\frac{10xy+12y^2}{(x+2y)(x+y)}=\frac{2y(5x+6y)}{(x+2y)(x+y)}$$

The above example is worked out in full. After a little practice such steps as (a) and (b) may be omitted

The common denominator should generally be left in factors, and the result reduced to its lowest terms

Example 3   Simplify $\dfrac{a^2-b^2}{ab+b^2}-\dfrac{a-b}{a+b}$

$$\text{The given expression}=\frac{(a-b)(a+b)}{b(a+b)}-\frac{a-b}{a+b}$$

$$=\frac{a-b}{b}-\frac{a-b}{a+b}$$

$$=(a-b)\left[\frac{1}{b}-\frac{1}{a+b}\right]$$

$$=(a-b)\frac{a+b-b}{b(a+b)}$$

$$=\frac{a(a-b)}{b(a+b)}$$

$$=\frac{a(a+b)-b(a-b)-b^2}{a^2-b^2}-\frac{a^2}{a^2+b^2}$$

(taking the first three fractions together)

$$=\frac{a^2-ab-ab+b^2-b^2}{a^2-b^2}-\frac{a^2}{a^2-b^2}$$

$$=\frac{a^2}{a^2-b^2}-\frac{a^2}{a^2+b^2}$$

$$=a^2\left(\frac{1}{a^2-b^2}-\frac{1}{a^2-b^2}\right)$$

$$=\frac{a^2(a^2+b^2-a^2+b^2)}{a^4-b^4}$$

$$=\frac{2a^2b^2}{a^4-b^4}$$

Example 2 Simplify $\dfrac{3}{x-a}-\dfrac{1}{x-3a}-\dfrac{3}{x-a}+\dfrac{1}{x+3a}$

The given expression $=\left(\dfrac{3}{x-a}-\dfrac{3}{x-a}\right)-\left(\dfrac{1}{x+3a}-\dfrac{1}{x-3a}\right)$ (rearranging the fractions)

$$=\frac{3x+3a-3x+3a}{x^2-a^2}+\frac{x-3a-x-3a}{x^2-9a^2}$$

$$=\frac{6a}{x^2-a^2}-\frac{6a}{x^2-9a^2}$$

$$=6a\left(\frac{1}{x^2-a^2}-\frac{1}{x^2-9a^2}\right)$$

$$=\frac{6a(x^2-9a^2-x^2+a^2)}{(x^2-a^2)(x^2-9a^2)}$$

$$=\frac{-48a^3}{(x^2-a^2)(x^2-9a^2)}$$

CHAPTER XXII

HARDER SIMPLE EQUATIONS INVOLVING FRACTIONS

123 The usual method of solution is to clear away the fractions by multiplying both sides of the equation by the L C M of the denominators

The work can often be shortened by sundry methods illustrated in the following worked-out examples

Example 1   Solve the equation $\dfrac{3}{4x-3}=\dfrac{2}{3x-5}$

Multiplying both sides by $(4x-3)(3x-5)$, the L C M of the denominators,
$$3(3x-5)=2(4x-3),$$
$$9x-15=8x-6,$$
$$x=9$$

Example 2   Solve the equation $\dfrac{3x}{x-1}-\dfrac{2x}{x+1}=\dfrac{x^2+10}{x^2-1}$

Multiplying both sides by $(x-1)(x+1)$,
$$3x(x+1)-2x(x-1)=x^2+10,$$
$$3x^2+3x-2x^2+2x=x^2+10,$$
$$5x=10,$$
$$x=2$$

Example 3 Solve the equation $\dfrac{2}{2x-1}-\dfrac{3}{3x+1}=\dfrac{3}{3x-1}-\dfrac{2}{2x+1}$

Simplifying each side of the equation separately,

$$\frac{2(3x+1)-3(2x-1)}{(2x-1)(3x+1)}=\frac{3(2x+1)-2(3x-1)}{(3x-1)(2x+1)},$$

$$\frac{6x+2-6x+3}{(2x-1)(3x+1)}=\frac{6x+3-6x+2}{(3x-1)(2x+1)},$$

$$1+\frac{2}{x-5}-1-\frac{2}{x-3}=1+\frac{2}{x-9}-1-\frac{2}{x-7}$$

Dividing both sides by 2

$$\frac{1}{x-5}-\frac{1}{x-3}=\frac{1}{x-9}-\frac{1}{x-7}$$

Simplifying each side separately,

$$\frac{(x-3)-(x-5)}{(x-5)(x-3)}=\frac{(x-7)-(x-9)}{(x-7)(x-9)},$$

i e $\dfrac{2}{(x-5)(x-3)}=\dfrac{2}{(x-7)(x-9)}$

Dividing both sides by 2, and multiplying up,

$$(x-7)(x-9)=(x-5)(x-3),$$
$$x^2-16x+63=x^2-8x+15$$
$$-8x=-48,$$
$$x=6$$

$$\text{for } (+2)^2 = 4, \quad \text{and} \quad (-2)^2 = 4$$

$$\sqrt{4} = 2 \quad \text{or} \quad -2,$$

∴, as it is written more shortly, $\sqrt{4} = \pm 2$

At present we will only deal with the positive root

A square is always positive, for by the rule of signs

$$a \times a = a^2,$$
$$(-a) \times (-a) = a^2,$$

i e whether a quantity is positive or negative, its square is positive

Hence we see that a negative quantity has no square root The square root of a negative quantity however has an interpretation, but this hardly comes into the province of Elementary Algebra

The square roots of simple algebraical expressions can be seen by inspection

$$\sqrt{(a^4b^2)} = a^2b$$
$$\sqrt{x^2y^4z^6} = xy^2z^3$$
$$\sqrt{16a^4} = 4a^2$$
$$\sqrt{\frac{81b^4}{x^2}} = \frac{9b^2}{x}$$

Examples   XXIV a

Write down, or read off, the positive square roots of the following

1 x^4	2 a^{10}	3 y^{16}	4 x^6y^4
5 a^8b^4	6 x^8y^6	7 $4a^2b^2$	8 $16a^4b^2$
9 $49x^4y^6z^8$	10 $\frac{4a^2}{b^2}$	11 $\frac{9x^4}{y^6}$	12 $\frac{81a^4b^6}{c^8}$
13 $\cdot01$	14 $\cdot25$	15 64	16 $\frac{1}{\cdot0001}$
17 $\frac{1}{16}$	18 $\frac{49}{36}$	19 $\cdot01b^4c^2$	20 $\frac{16a^2}{4b^4}$
21 $1\cdot21a^6c^{10}$	22 $\frac{16}{49}x^{12}y^{16}$	23 $\frac{a^4}{81b^2}$	24 $\frac{\cdot0064x^4}{\cdot0001y^{12}}$
25 $9(a-b)^n$	26 $\frac{121}{9}(2x+y)^2$	27 $\cdot01(10x+10y)^2$	

125 The square of a simple expression is also a simple expression

E g $(4a^2b^2)^2 = 16a^4b^4$

We know also that the square of a binomial expression is a trinomial expression

E g $(x+2)^2 = x^2 + 4x + 4$
$$(2x+3)^2 = 4x^2 + 12x + 9$$

Thus we see that a binomial expression has no square root

126 The square root of a trinomial expression which is a square can usually be determined by inspection

$$(a \pm b)^2 = a^2 \pm 2ab + b^2$$

Hence all trinomials which are perfect squares must be of the form $a^2 + 2ab + b^2$

Thus
$$4x^2 + 12xy + 9y^2 = (2x)^2 + 2(2x)(3y) + (3y)^2$$
$$\sqrt{4x^2 + 12xy + 9y^2} = 2x + 3y$$
$$\sqrt{4x^2 - 12xy + 9y^2} = 2x - 3y$$

The form of the square of a binomial $(a^2 \pm 2ab + b^2)$ is of great importance

Consider the expression

$$x^2 + pax + a^2$$

By comparing this with the above we see that if it has a square root, that root must be $x + a$

But
$$(x + a)^2 = x^2 + 2ax + a^2,$$

if $x^2 + pax + a^2$ is a perfect square,

p must be equal to 2

46 $4x^2 + 25y^2$ **47** $(a+b)^2 + 2(a+b)$

48 Determine the value of p if $x^2 - 4px + 16$ is a perfect square

49 For what value of a will $x^2 - 2x + a$ be a perfect square?

50 What value of p will make $x^2 + 6pxy + q^2y^2$ a perfect square?

127 *To find the square root of any compound expression*

The method depends upon the fact that the square of $a+b$ is $a^2 + 2ab + b^2$, which may be written in the form

$$a^2 + b(2a+b) \tag{1}$$

Let us take an easy example

The first term in the square root of $36x^2 - 84xy + 49y^2$ is evidently $6x$

$$
\begin{array}{l}
36x^2 - 84xy + 49y^2\,(\,6x \\
36x^2 \\
\hline
\quad - 84xy + 49y^2
\end{array}
$$

Subtracting its square, *i e* $36x^2$, from the given expression, the remainder is $-84xy + 49y^2$, which may be written

$$-7y(2 \times 6x - 7y)$$

Comparing this with (1), we see that in this case a is $6x$, and therefore b is $-7y$

Hence we have the following rule

Having obtained the first term, (6x), double it, (12x), and divide the first term ($-84xy$) of the remainder by it   The quotient ($-7y$) is the second term of the square root

The full work is best arranged as below

$$
\begin{array}{l}
36x^2 - 84xy + 49y^2\,(\,6x - 7y \\
36x^2 \\
\hline
\quad\quad - 84xy + 49y^2 \\
(12x - 7y) \times (-7y) = - 84xy + 49y^2
\end{array}
$$

Explanation Having obtained the first term of the square root, $6x$, we double it, $12x$, and divide it into $-84xy$, the first

term of the remainder when $(6x)^2$ is subtracted The quotient $(-7y)$ is the second term of the answer

Add $-7y$ to $12x$ and multiply the result by $-7y$, placing the result $-84xy + 49y^2$ under the remainder

If the student carefully compares the following with the expression $a^2 + b(2a + b)$, he will see the reasons for the different steps

$$a^2 + 2ab + b^2 \; (\; a$$
$$a^2$$
$$\overline{\quad\; 2ab + b^2\quad}$$
$$(2a + b) \times b = \underline{2ab + b^2}$$

128 *Find the square root of*

$$25x^4 - 30px^3 + 49p^2x^2 - 24p^3x + 16p^4$$

$$25x^4 - 30px^3 + 49p^2x^2 - 24p^3x + 16p^4 \; (\; 5x^2 - 3px$$
$$25x^4$$
$$\overline{\quad -30px^3 + 49p^2x^2\quad}$$
$$(10x^2 - 3px) \times (-3px) = \underline{-30px^3 + \; 9p^2x^2}$$
$$40p^2x^2 - 24p^3x + 16p^4$$

Thus far the work is exactly similar to that in the previous examples, the reasons being the same

Thinking once more of the expression $a^2 + b(2a + b)$, we see that if the given expression has a square root, the remainder $40p^2x^2 - 24p^3x + 16p^4$ must be of the form $b(2a + b)$, remembering that now a is $5x^2 - 3px$

We therefore *repeat the process of the first step*

Double $5x^2 - 3px$, obtaining $10x^2 - 6px$

$40p^2x^2 - 10x^2 = 4p^2$ gives us the next term of the answer

Add this to $10x^2 - 6px$, obtaining $10x^2 - 6px + 4p^2$, multiply this by $4p^2$, and place the result under the remainder

The example is worked out in full below

$$25x^4 - 30px^3 + 49p^2x^2 - 24p^3x + 16p^4 \big(5x^2 - 3px$$
$$25x^4 \qquad\qquad\qquad\qquad\qquad\qquad\quad + 4p^2$$
$$\overline{\quad -30px^3 + 49p^2x^2\quad}$$
$$(10x^2 - 3px) \times (-3px) = \underline{-30px^3 + \; 9p^2x^2}$$
$$40p^2x^2 - 24p^3x + 16p^4$$
$$(10x^2 - 6px + 4p^2) \times 4p^2 = \underline{40p^2x^2 - 24p^3x + 16p^4}$$
$$5x^2 - 3px + 4p^2 \text{ is the reqd sq root}$$

129 The square root of a compound expression can often be
seen by re-arrangement and inspection.

$$x^4 - 2x^3 - x^2 + 2x + 1$$
$$= x^4 - 2x^3 - 2x^2 + (x^2 + 2x + 1)$$
$$= x^4 - 2x^2(x-1) + (x+1)^2 \quad [a^2 - 2ab + b^2]$$
$$= [x^2 - (x+1)]^2,$$
$$\therefore \sqrt{x^4 - 2x^3 - x^2 + 2x - 1} = x^2 - x - 1$$

$$a^2 + b^2 + c^2 - 2bc - 2ac + 2ab$$
$$= a^2 + 2a(b-c) - b^2 + c^2 - 2bc$$

(arranging in descending powers of a)
$$= a^2 + 2a(b-c) + (b-c)^2$$
$$= (a-b-c)^2,$$
$$\therefore \sqrt{a^2 + b^2 + c^2 - 2bc - 2ac + 2ab} = a + b - c$$

SQUARE ROOT OF NUMERICAL QUANTITIES

$$14^2 = 196, \quad 18^2 = 4 \times 81 = 324,$$

THE DETERMINATION OF THE SQUARE ROOTS OF NUMBERS BY GRAPHICAL METHODS

133 The student must first familiarize himself with the graph of the equation $y = x^2$

Trace the graph of $y = x^2$

When

$x = 0$	± 1	± 2	± 3	± 4	± 5	
$y = 0$	1	4	9	16	25	
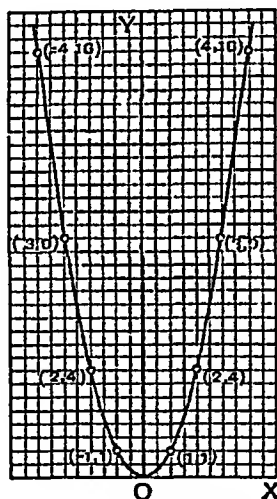

Joining these points, we have the graph reqd, which we see is a curve

For every value of y there are two equal and opposite values of x

the curve is symmetrical about the axis of y

Moreover, as x increases indefinitely, y also increases indefinitely

the parts of the curve on either side of OY meet only at the origin

Such a curve is called a parabola

N B—In the above we have taken twice the length of the side of a square to denote unity

We observe that when x is greater than unity, the y value increases much more rapidly than the x value   This is well seen from the table of corresponding values of x and y below

When

$x=$	5	6	7	8	9	10	11	
$y=$	25	36	49	64	81	100	121	

**134** A better curve for working purposes will be obtained if we take 10 times the side of a square to denote unity for the abscissae, and one side of a square to denote unity for the ordinates

Employing these units, we obtain the curve shown below
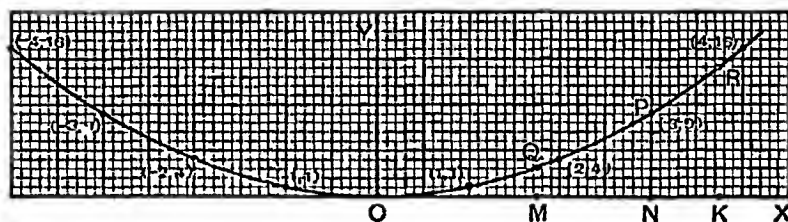

Thus at P, the abscissa ON = 30 times the side of a sq = 3 units
and   the ordinate PN = 9 times the side of a sq = 9 units

The effect of using different units for the x and y values in this way, is the same as uniformly stretching the paper in a direction parallel to the axis of x If we took the larger unit for the y values, it would be the equivalent of stretching the paper parallel to the axis of y

It will sometimes be found convenient to take the x unit still larger

In connection with square roots, the important thing to observe is that since $y = x^2$, or $x = \sqrt{y}$, for every point on the curve, the abscissa of any point on it is the square root of the corresponding ordinate

In the curve shown above take the point Q when the ordinate is 3 and draw the ordinate QM

Now at every pt on the curve $y = x^2$,

at Q $3 = OM^2$, for there $y = 3$ and $x = OM$,

$$OM = \sqrt{3}$$

But from the figure we see that OM lies between 1 7 and 1 8, and somewhat nearer 1 7 than 1 8,

$\sqrt{3} = 1\,7$ correct to one decimal place

Again take the pt R where RK, the ordinate, $= 14$

$$14 = OK^2,$$

$\sqrt{14} = OK = 3\,7$ correct to one decimal place

135 *Construct a graph from which the square roots (correct to two decimal places) of numbers between 16 and 25 may be read off*
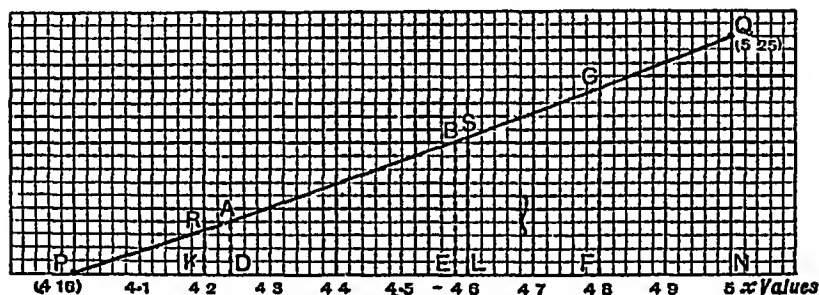

We must draw the graph of $y = x^2$, and use a large unit for x values, for x has to be determined accurately to two decimal places

We shall only need to draw that part of the curve where x lies between 4 and 5

Take 50 sides of squares to represent unity in the x values, and 2 sides of squares to represent unity in the y values

In the curve $y = x^2$, when $x = 4$, $y = 16$,

and when $x = 5$, $y = 25$

Let P be the pt $(4, 16)$ and Q the pt $(5, 25)$ so that PN in the figure representing unity is equal to 50 sides of squares, and QN representing 9 is equal to 18 sides of squares

(N B—QN is the difference of the ordinates of P and Q, and therefore $= 25 - 16 = 9$ units)

When $x = 4\ 2,\ y = x^2 = (4\ 2)^2 = 17\ 64,$

$17\ 64 - 16 = 1\ 64$ units $= 3\ 28$ sides of sqs

Hence estimating the value of 28, R in the fig is the pt $(4\ 2, (4\ 2)^2)$

(RK in the fig $=$ the diff of the ordinates of R and P

$= 17\ 64 - 16 = 1\ 64$ units $= 3\ 28$ sides of sqs)

Again, when $x = 4\ 6,\ y = x^2 = (4\ 6)^2 = 21\ 16,$

estimating the value of 16, S in the fig is the pt $(4\ 6, (4\ 6)^2)$

(Here again, SL $=$ the diff of the ordinates of S and P

$= 21\ 16 - 16 = 5\ 16$ units $= 10\ 32$ sides of sqs)

The curve through the pts P, R, S, Q is evidently so nearly a str line that we need find no more pts on the curve

Join the pts P, R, S, Q by the continuous curve as shown in the figure

To find $\sqrt{18}$ from this graph we must take the pt whose ordinate is 18, i e the pt A   (N B—AD $= 18 - 16 = 2$ units $= 4$ sides of a sq)

From the fig we see that the abscissa of this pt is $4 + $PD, which is equal to $4\ 24$,

$$\sqrt{18} = 4\ 24$$

To find $\sqrt{21}$, we must take the pt whose ordinate is 21, i e the pt B   (N B—BE $= 21 - 16 = 5$ units $= 10$ sides of a sq)

From the graph the abscissa of this point $= 4 + $PE $= 4\ 58$,

$$\sqrt{21} = 4\ 58$$

To find $\sqrt{23}$, we must take the pt whose ordinate is 23, i e the pt C,

$$\sqrt{23} = 4 + \text{PF} = 4\ 80$$

The roots of other numbers between 16 and 25 can be read off in the same way

136 The following geometrical methods may be used for determining the values of square roots in simple cases

Example   To find the value of $\sqrt{5}$
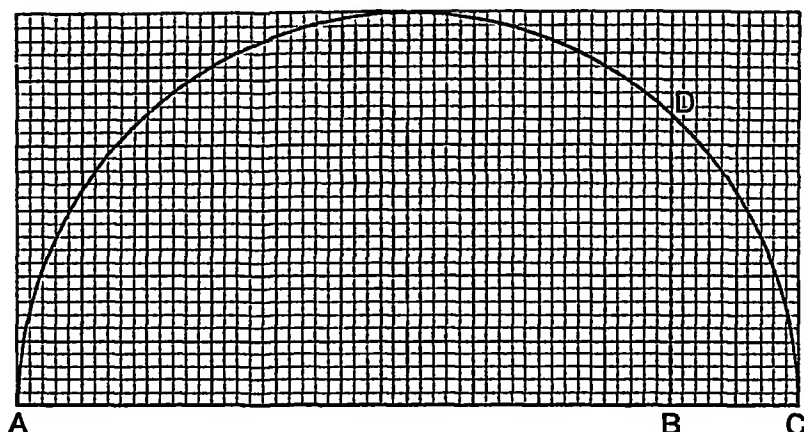

First Method   Take AB 5 units long, and produce it to C making BC equal to one unit   On AC as diameter describe the circle ADC   At B draw BD perp to AC, meeting the circle at D

From geometry we know that

$$DB^2 = AB \cdot BC = 5,$$

$$DB = \sqrt{5}$$

From the diagram $\sqrt{5} = 2\ 24$ approx

(If squared paper is not used, DB must be measured)

Second Method   On AB, 5 in long, as diameter describe a circle

In AB take a pt D 1 in from A, and draw DC perp to AB to meet the circle at C   Join AC   With centre A and radius AC describe a circle cutting AB at E.

By geometry $AC^2 = AD \cdot AB = 5,$

$$AC = \sqrt{5},$$

$$AE = AC = \sqrt{5},$$

and if squared paper is used we can read off the value of $\sqrt{5}$ from the diagram

Pythagoras' Theorem, which proves that the square on the hypotenuse of a right angled triangle is equal to the sum of the squares on its sides, may be sometimes used with advantage

Thus to find $\sqrt{10}$, $10 = 1^2 + 3^2$, draw AB 3 units long, AC 1 unit long at rt angles to AB   Join BC $BC = \sqrt{10}$ units long

137. *Draw the graph of* $y = x^3$
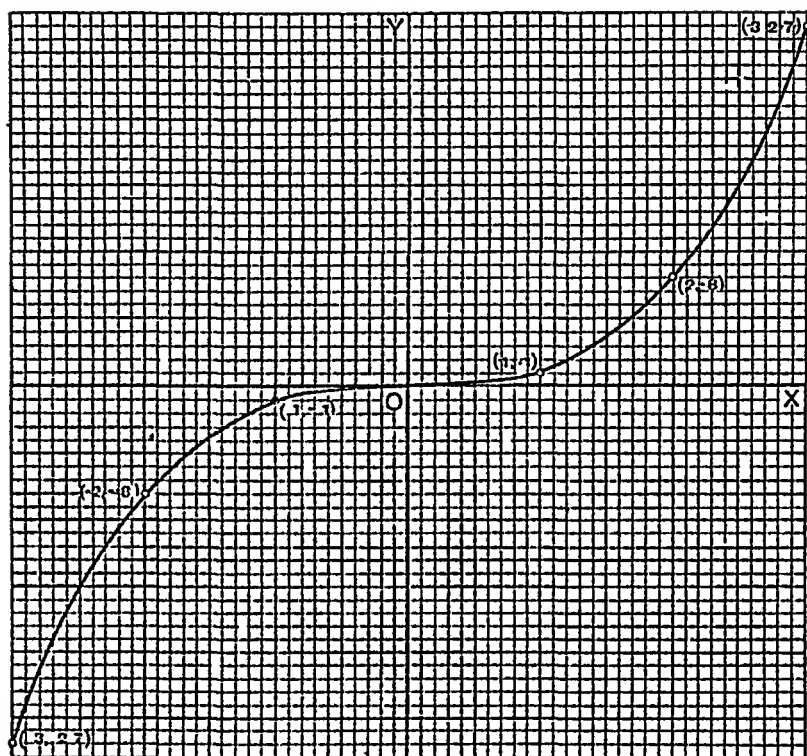

Use for the y values a unit one-tenth of that for the x values

When

$x = 1$	2	3	4	5		inches
$y = 1$	8	27	64	125		tenths of an inch

$x = -1$	-2	-3		inches
$y = -1$	-8	-27		tenths of an inch

Plot these points and we have the graph reqd

We see that the curve lies entirely in the first and third quadrants, and that the parts of the curve in those quadrants are similar

For values of x greater than 1 or less than -1, as the numerical value of x increases, that of y increases much more rapidly, but for values of x between 1 and -1 the reverse happens   This shows that the axis of x is a tangent to the curve at the origin

As x varies continuously from $-\infty$ through 0 to $+\infty$, y also varies continuously from $-\infty$ through 0 to $+\infty$

From this graph we can read off cube roots and cubes of numbers

138 *To construct a graph from which the cube root of any number between 64 and 125 may be written down, correct to two decimal places*
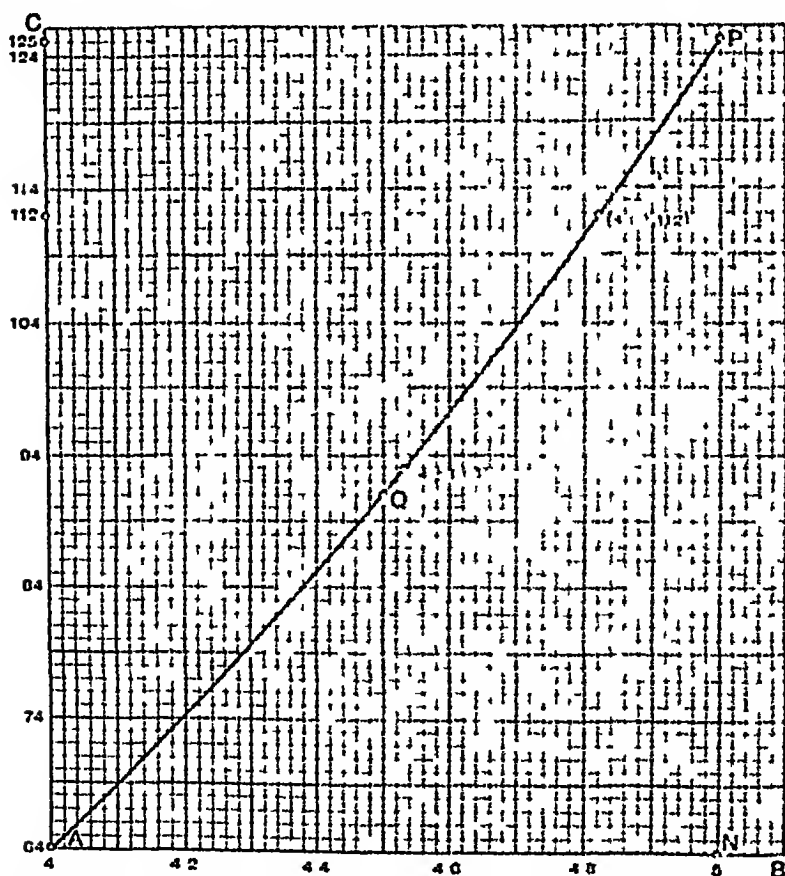

Take a piece of squared paper ruled in inches and tenths of an inch

Let the pt A denote the pt whose co ors are (4, 64)

In the horizontal line AB take 1 in to represent 2, so that AN (5 in long) represents unity

In the vertical line AC take an inch to represent 10

On the paper plot the point (5, 125) P

$(4\ 5)^3 = 91\ 125$ plot the pt $(4\ 5, 91\ 125)$ Q, estimating the value of 125

Join the pts A, Q, P by an even curve

This curve will be seen to be part of the graph of $y = x^3$

we can read from it the values of the cube roots of numbers between 64 and 125

$E g$ $\sqrt[3]{112} = 4\ 82,\ \sqrt[3]{93} = 4\ 53$

NOTE —Great accuracy can be obtained in the above if a few more points are plotted , e g $[(4\ 2), (4\ 2)^3]$, $[(4\ 8), (4\ 8)^3]$

CHAPTER XXV

QUADRATIC EQUATIONS

139 When an equation contains the square of the unknown quantity, and no higher power, it is called a **quadratic equation,** or an equation of the second degree

$$\left. \begin{array}{l} x^2 - 7x + 12 = 0, \\ 6x^2 = 7x + 3, \\ 12 = 23x - 5x^2, \\ x^2 - 4 = 0 \end{array} \right\} \text{ are examples of such}$$

140. Solution of quadratics by factorization

Let us consider the equation $\quad x^2 - 7x + 12 = 0$

It may be written $\qquad\qquad (x-3)(x-4)=0$

We notice that when $\qquad\qquad\qquad x = 3,$

the left-hand side $= (3-3)(3-4)$

$$= 0 \times (-1) = 0,$$

$i\,e$ the equation is satisfied, or 3 is a root of the equation

Also when $\qquad\qquad\qquad x = 4,$

the left-hand side $= (4-3)(4-4)$

$$= 1 \times 0 = 0,$$

4 also is a root of the equation

It will be proved later on that every quadratic equation has two roots and only two

$N\,B$ —Every *multiple* of 0 is 0

$$6 \times 0 = 0, \qquad 1000 \times 0 = 0,$$
$$0 \times a = 0, \qquad 0 \times x^3 = 0$$

Examples XXV a

Write down the roots of the following equations

1 $(x-1)(x-2)=0$ 2 $(x-1)(x+1)=0$ 3 $(x-a)(x-b)=0$

4 $x(x-1)=0$ 5 $(x+2)(x+3)=0$ 6 $(x+a)(x-b)=0$

7 $(x+2)x=0$ 8 $(x-2a)(x-b)=0$ 9 $(x+a)(x-2b)=0$

10 $(x-\frac{1}{2})(x+\frac{3}{4})=0$ 11 $(x+\frac{1}{5})(x+\frac{3}{9})=0$ 12 $x(x+\frac{1}{3})=0$

13 $\left(x-\frac{a}{2}\right)\left(x-\frac{b}{3}\right)=0$ 14. $(x-\overline{a+b})(x-\overline{a-b})=0$

Write down the roots of the following equations

15 $\left(x-\dfrac{a+b}{2}\right)\left(x+\dfrac{c+d}{2}\right)=0$ 16 $(x-\overline{p-2q})(x-\overline{2p-q})=0$

17 $\{x-2(a+b)\}\{x+3(a-b)\}=0$ 18 $(x-a^2)(x+b^2)=0$

√19 $\{x+(a-b)^2\}\{x-(a+b)^2\}=0$ 20 $(x-3)^2=0$ 21 $x(x-a)=0$

22 $x(x+4)=0$ 23 $(x+a)^2=0$ 24 $(x+2a)^2=0$

141 *Solve the equation* $x^2=x+20$

Transposing all the terms to the left-hand side (or subtracting $x+20$ from both sides)

$$x^2-x-20=0,$$

factorizing, $$(x-5)(x+4)=0,$$

$$x=5 \text{ or } -4$$

Verification When $x=5$, $x^2-x-20=25-5-20$

$$=0,$$

5 is a root of the equation

When $x=-4$, $x^2-x-20=(-4)^2-(-4)-20$

$$=16+4-20=0,$$

-4 is also a root

Solve the equation $4x^2-16x=84$

Transposing 84 to the left hand side,

$$4x^2-16x-84=0$$

Dividing both sides by 4, $x^2-4x-21=0,$

factorizing, $$(x-7)(x+3)=0,$$

$$x=7 \text{ or } -3$$

Verification When $x=7$

$$4x^2-16x-84=4\times49-16\times7-84$$

$$=196-112-84$$

$$=0,$$

7 is a root of the equation

When $x=-3$, $4x^2-16x-84=4\times9-16(-3)-84$

$$=36+48-84$$

$$=0,$$

-3 is also a root

142 When an equation contains the square of the unknown quantity, and no first power of the unknown quantity, it is called

a **pure quadratic** If it contains both the square and the first power of the unknown, it is called an **adfected quadratic**

$x^2 - 4 = 0$ and $6x^2 = 54$ are examples of pure quadratics

$x^2 - 7x + 12 = 0$ is an adfected quadratic

Pure quadratics are easily solved by factorization

Solve the quadratic $6x^2 = 54$

Dividing both sides by 6, $x^2 = 9$

Adding 9 to both sides, $x^2 - 9 = 0$,

$\qquad i\,e \quad (x-3)(x+3) = 0,$

$\qquad\qquad x = 3 \text{ or } -3$

Or we might proceed thus,

$\qquad\qquad x^2 = 9 \text{ as before}$

Taking the square root of each side

$\qquad\qquad x = \pm 3$

143 *Solve the equation* $x^2 = 12 - x$

Transposing all terms to the left-hand side (or subtracting $12 - x$ from both sides),

the equation becomes $x^2 + x - 12 = 0$

Factorizing, $(x + 4)(x - 3) = 0,$

from which we see that -4 and 3 are the roots reqd

Verification   When $x = -4,$

$\qquad$ the left-hand side $= (-4)^2 = 16$,

$\qquad$ the right-hand side $= 12 - (-4) = 16$,

$\qquad\qquad -4$ is a root

When $x = 3$,   the left-hand side $= (3)^2 = 9$,

$\qquad$ the right-hand side $= 12 - 3 = 9$

$\qquad\qquad 3$ is also a root

Examples   XXV b

Solve the following equations, verifying the solutions in each case

1 $x^2 - 7x + 10 = 0$	2 $x^2 - 5x + 6 = 0$	3 $x^2 - 4 = 0$
4. $x^2 - 3x = 0$	5 $x^2 + 4x + 3 = 0$	6 $x^2 + 4x - 5 = 0$
7 $x^2 = 8x - 7$	8 $x^2 - 2 = x$	9 $x^2 - 3 = 1$
0 $x^2 + 10 = 11x$	11 $4x = 45 - x^2$	12. $12x - 27 = x^2$
3 $x^2 = 20 - x$	14 $x^2 = 7x$	15 $2x^2 - 1 = 1$
6 $x^2 - 4x + 4 = 0$	17. $x^2 + 3x = 0$	18. $21 + 10x + x^2 = 0$

Solve the following equations, verifying the solutions in each case

19   $14x + 15 = x^2$ 20 $40 = 3x + x^2$ 21 $x^2 + 225 = 30x$

22   $2x^2 - 3 = 15$ 23 $4x^2 = 8x$ 24 $3x^2 + 21x = 0$

25   $103x = x^2 + 102$ 26 $x^2 + 16x + 15 = 0$

144   Let us take the equation $2x^2 - 11x + 12 = 0$

It may be written $(2x - 3)(x - 4) = 0$

We see that if $2x - 3 = 0$, i e if $x = \frac{3}{2}$, the equation is satisfied, for $0 \times (\frac{3}{2} - 4) = 0$

Also if $x - 4 = 0$, i e if $x = 4$, the equation is again satisfied,

$\underset{\sim}{\frac{3}{2}}$ and 4 are the roots of the equation

Solve the equation $x^2 = 2(x + 12)$

Removing the brackets $x^2 = 2x + 24$

Transposing all terms to the left-hand side,

$$x^2 - 2x - 24 = 0$$

Factorizing, $(x - 6)(x + 4) = 0$,

6 and -4 are the reqd roots.

Solve the equation $x^2 - 4x + 4 = 0$

Factorizing, $(x - 2)(x - 2) = 0$,

in this case the roots are equal and each of them is 2

145   If fractions or brackets occur in the given equation, they should first be cleared away

Example 1   Solve the equation $3x - 8 = \frac{x^2}{4}$

Multiplying both sides by 4, $12x - 32 = x^2$

Transposing all terms to the left hand side (or subtracting x^2 from both sides), $12x - 32 - x^2 = 0$

Re arranging and changing signs throughout [this is permissible, for if $a = b$, $-a = -b$, if $a = 0$, $-a = 0$],

$$x^2 - 12x + 32 = 0$$

Factorizing, $(x - 4)(x - 8) = 0$,

4 and 8 are the reqd roots, or $x = 4$ or 8

Verification   When $x = 4$, the left hand side $= 3 \times 4 - 8 = 4$

the right-hand side $= \frac{(4)^2}{4} = 4$,

4 is a root

When $x = 8$, the left hand side $= 3 \times 8 - 8 = 16$

the right-hand side $= \frac{(8)^2}{4} = \frac{64}{4} = 16$,

8 is also a root

Example 2   Solve the equation $\dfrac{7}{3x-1}-\dfrac{4}{x+1}=\dfrac{1}{4}$

Multiplying both sides by $4(3x-1)(x+1)$, the L C M of the denominators,
$$28(x+1)-16(3x-1)=(x+1)(3x-1),$$
$$28x+28-48x+16=3x^2+2x-1$$
Transposing and arranging, $-3x^2-22x+45=0,$
$$3x^2+22x-45=0,$$
$$(3x-5)(x+9)=0,$$
$\tfrac{5}{3}$ and -9 are the reqd roots

It is important to observe that if $x-a$ is a factor of both sides of an equation, a is a root of the equation
This is at once seen by substitution

Example 3   Solve the equation $2(2x-5)+7x(2x-5)=0$
$2x-5$ is a factor throughout , $2x-5=0$ gives a root
whence $x=\tfrac{5}{2}$
Having divided by $2x-5$, we have left
$$2+7x=0$$
whence $x=-\tfrac{2}{7}$,
the reqd roots are $\tfrac{5}{2}$ and $-\tfrac{2}{7}$

Examples   XXV c

Write down the roots of the following quadratic equations

1    $(2x-3)(x-4)=0$ 2 $(3x+1)(2x-1)=0$ 3 $(3x+4)(5x+6)=0$
4    $x(7x+9)=0$ 5 $(5x-7)(6x+1)=0$ 6 $(7x-8)^2=0$
7    $(2x-a)(2x-b)=0$ 8 $(5x+a)(6x+b)=0$
9    $(2x-\overline{a+b})(3x-\overline{c+d})=0$ 10 $3(4x+5)(2x-9)=0$

Solve the following equations

11    $x^2=2-x$ 12 $8x-x^2=15$ 13 $x^2=4(x+8)$
14    $2(5x-12)=x^2$ 15 $x(x-4)=5$ 16 $4x^2=1$
17    $x^2-4x=4(x-4)$ 18 $1+2x^2=3x$ 19 $x(x+4)=6(x+4)$
20    $5x^2+17x=0$ 21 $x-10=x(x-10)$ 22 $4x(x+1)+1=0$
23    $x^2+4\,8x+2\,87=0$ 24 $x+\dfrac{1}{x}=2$ 25 $x-\dfrac{9}{2}+\dfrac{2}{x}=0$
26    $(2x-1)(3x+1)=11$ 27. $2x^2+\dfrac{13x}{2}=6$ 28 $5x(2x-3)+7(2x-3)=0$
29    $x-1=\dfrac{2}{x}$ 30 $(2x+1)(x+8)=27$ 31 $\dfrac{x+10}{x-5}-\dfrac{10}{x}=\dfrac{11}{6}$
32. $150x^2=299x+2$ 33 $(5x-3)(3x+1)=1$ 34 $6(4x+5)+\dfrac{7}{x}(4x+5)=0$
35    $13x^2-6x-7=0$ 36 $x+35=70x^2$ 37. $9x^2=18x+16$
88    $\dfrac{1}{x-1}-\dfrac{1}{x+3}=\dfrac{1}{35}$

SOLUTION OF QUADRATICS BY COMPLETING SQUARES

146 Take the equation $a^2 + 2ab = 0$

Adding b^2 to both sides, $a^2 + 2ab + b^2 = b^2$,

$$\imath c \quad (a+b)^2 = b^2$$

The addition of b^2 to both sides **completed the square** on the left-hand side

Take the equation $x^2 - 6x = 0$

Adding 9 to both sides, $x^2 - 6x + 9 = 9$,

$$(x - 3)^2 = 3^2$$

Again the left-hand side becomes a complete square

More generally, to complete the square on the left of the equation $x^2 - 2ax = 0$ we must add a^2 to both sides

The equation becomes $x^2 - 2ax + a^2 = a^2$,

$$\text{or } (x - a)^2 = a^2$$

$$x^2 + 8x \quad \text{becomes } (x + 4)^2 \text{ by adding } 16, \imath e \ 4^2 \qquad (1)$$
$$x^2 - 2cx \qquad\quad (x - c)^2 \qquad\qquad c^2 \qquad\qquad\qquad (2)$$
$$x^2 + 10x \qquad\quad (x + 5)^2 \qquad\qquad 5^2 \qquad\qquad\qquad (3)$$

Thus we observe that any expression of the form $x^2 \pm 2px$ becomes a complete square when we add the square of half the coefficient of x.

$$\text{In (1) we add } \left(\frac{8}{2}\right)^2$$

$$\text{In (2)} \qquad\quad \left(-\frac{2c}{2}\right)^2$$

$$\text{In (3)} \qquad\quad \left(\frac{10}{2}\right)^2$$

147 Let us now employ this to solve quadratic equations

Example 1   Solve the quadratic $x^2 + 4x = 32$

Adding the sq of half the coeff of x to both sides,

$$x^2 + 4x + \left(\frac{4}{2}\right)^2 = 32 + \left(\frac{4}{2}\right)^2,$$
$$\imath e \ \ x^2 + 4x + (2)^2 = 36,$$
$$(x + 2)^2 = 36$$

Taking the square root of both sides,

$$x + 2 = \pm 6 \qquad\qquad\qquad (1)$$

With the positive sign $\qquad x + 2 = 6,$
$$x = 4$$

With the negative sign $x+2=-6$,

$$x=-8,$$

4 and -8 are the reqd roots

In connection with (1) we at first sight think we ought to say

$$\pm(x+2)=\pm6,$$

for $\pm(x+2)$ is the sq root of $(x+2)^2$ just as ±6 is the sq root of 36

This however is unnecessary, as we see if we take the *four* different cases separately

With positive signs on both sides, $x+2=6,$ $x=4$ } the same result
      negative $-x-2=-6,$ $x=4$ }

With the positive sign on the left and the negative sign on the right,

$$x+2=-6, \ x=-8$$

With the negative sign on the left and the positive sign on the right,

$$-x-2=+6,$$

$$x+2=-6, \ x=-8, \text{ again the same result}$$

Thus it is sufficient if we attach the double sign ($\pm$) to one side
We always attach it to the numerical square root

148 Before completing squares the coefficient of x^2 must be reduced to unity

Solve the equation $22-x=6x^2$

Re arranging by transposition, $6x^2+x=22$

Dividing both sides by 6 to make the coefficient of x equal to unity,

$$x^2+\frac{x}{6}=\frac{22}{6}$$

Adding the sq of half the coeff of x, i e $\left(\frac{1}{12}\right)^2$, to both sides,

$$x^2+\frac{x}{6}+\left(\frac{1}{12}\right)^2=\frac{22}{6}+\frac{1}{144},$$

$$\left(x+\frac{1}{12}\right)^2=\frac{528+1}{144}$$

$$=\frac{529}{144}$$

Taking the sq root of both sides,

$$x + \frac{1}{12} = \pm \frac{23}{12}$$

With the positive sign $x + \frac{1}{12} = \frac{23}{12},$

$$x = \frac{23 - 1}{12} = \frac{11}{6}.$$

With the negative sign $x + \frac{1}{12} = -\frac{23}{12},$

$$x = \frac{-23 - 1}{12} = -2 ;$$

$\frac{11}{6}$ and -2 are the reqd roots

149   *To solve the general quadratic $ax^2 + bx + c = 0$*

$$ax^2 + bx = -c,$$

$$x^2 + \frac{bx}{a} = -\frac{c}{a}$$

Adding the square of half the coeff of x to both sides,

$$x^2 + \frac{bx}{a} + \left(\frac{b}{2a}\right)^2 = \frac{b^2}{4a^2} - \frac{c}{a}$$

$$= \frac{b^2 - 4ac}{4a^2}$$

Taking the sq root of both sides,

$$x + \frac{b}{2a} = \frac{\pm\sqrt{b^2 - 4ac}}{2a},$$

$$\mathbf{x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}}$$

The above formula may be used for the solution of any quadratic equation

There are therefore three methods of solving quadratics

(1) by factorization,   (2) by completing squares,

(3) by using the formula $\dfrac{-b \pm \sqrt{b^2 - 4ac}}{2a}$

The student should have considerable practice in all three methods

When the factors cannot be seen *readily*, the second or third method should be employed

Examples XXV

Solve the equations

1 $6x^2 = 2 - x$

2 $1 - 26x^2 = 11x$

3 $x + 1 = 156x^2$

4. $5x^2 = 4x + 1$

5 $3x^2 + 10 = 17x$

6 $7x^2 + 32x = 15$

7 $2x^2 + 19x + 9 = 0$

8 $(x-1)^2 = 16$

9 $2(x^2 + 1) - 5x = 0$

10 $11x = 3(2x^2 + 1)$

11 $3(x-1)(x+1) = 8x$

12 $(x-1)(x+1) = \dfrac{7x}{12}$

13 $15 = 4(3x^2 + 2x)$

14 $(2x-1)^2 = 25$

15 $(3x - \tfrac{1}{2})^2 = 49$

16 $3x(5x-1) = 4(x+9)$

17 $25x^2 - 7x = 86$

18 $5x - 11 = x(5x - 11)$

19 $13x + 9 = 10x^2$

20 $\left(\dfrac{x}{2} - 5\right)^2 - 36 = 0$

21 $3(3x+4) + 5x(3x+4) = 0$

22 $\dfrac{2x-3}{2} = \dfrac{4x-6}{x}$

23 $x(x-1) + \dfrac{1}{2}(x-1) = 0$

24. $\dfrac{2x-3}{5} + \dfrac{2(2x-3)}{3x} = 0$

25 $7(3x-6) + 11x(2x-4) - 3x(5x-10) = 0$

26 $\dfrac{2}{3(x-1)} - \dfrac{3}{2x+1} = \dfrac{1}{15}$

27 $\dfrac{6}{x-2} = \dfrac{5}{x-4} - \dfrac{6}{x-3}$

28 $\dfrac{x-1}{x+1} + \dfrac{x-3}{x+3} = \dfrac{2x+1}{2x+2}$

29 $\dfrac{x}{5+x} + \dfrac{7}{6-4x} = \dfrac{x-7}{x-6}$

30 $\dfrac{3x+4}{5} - \dfrac{30-2x}{x-6} = \dfrac{7x-14}{10}$

31 $\dfrac{2}{x-2} - \dfrac{3}{x-3} = \dfrac{4}{x-4} - \dfrac{5}{x-5}$

32 $\dfrac{2}{x+3} + \dfrac{x+3}{2} = \dfrac{10}{3}$

33 $\dfrac{2x}{x-1} + \dfrac{3x-1}{x+2} - \dfrac{5x-11}{x-2} = 0$

34. $\dfrac{x-3}{x+3} - \dfrac{x+3}{x-3} + 6\tfrac{6}{7} = 0$

When the quantity under the radical sign $(\sqrt{\ })$ is not a perfect square, the *approximate* values of the roots should be found by finding the square root to a few decimal places

Thus if $\qquad x = \dfrac{9 \pm \sqrt{21}}{10}$,

$$x = \frac{9 \pm 4\,583}{10} \text{ (for } \sqrt{21} = 4\,583 \text{)}$$

$\qquad\qquad = 1\,36,\ \text{or}\ \ 44,\ \text{correct to two decimal places.}$

Examples   XXV e

When the exact values of the roots of the following equations cannot be found, give results *correct to two decimal places*, i e to the nearest hundredth

Solve

1 $x^2 - 2x = 1$ **2** $x^2 = 2(1 - x)$

3 $x(x - 3) = x - 1$ **4** $x = \dfrac{x + 4}{x - 1}$

5 $5x^2 - 9x - 4 = 0$ **6** $\dfrac{x + 1}{x + 2} + \dfrac{x - 3}{x - 4} = 0$

7 $x^2 = \sqrt{3}(2x - \sqrt{3})$ **8** $\dfrac{1}{x + 3} + \dfrac{1}{x + 6} + \dfrac{1}{x + 9} = 0$

9 $\dfrac{2x - 1}{3x + 2} + \dfrac{x - 3}{x + 1} = 0$ **10** $\dfrac{x - 1}{x^2 + 3x + 2} + \dfrac{x - 3}{x^2 + 5x + 6} = \dfrac{1}{x + 2}$

11 $2(x - 1) = \dfrac{4 - 5x}{x + 1}$ **12** $\dfrac{1}{x - 2} + \dfrac{1}{x - 3} + \dfrac{1}{x - 4} = 0$

13 $\dfrac{3x + 1}{3x - 1} - \dfrac{3x - 1}{3x + 1} = 2$ **14.** $x^2 - \sqrt{3}x - 6 = 0$

MISCELLANEOUS FORMS OF QUADRATIC EQUATIONS

150   Example 1   Solve $\dfrac{x + 2}{x - 2} - \dfrac{x - 3}{x + 3} = \dfrac{x + 4}{x - 4} - \dfrac{x - 1}{x + 1}$

Simplifying each side separately,

$$\frac{x^2 + 5x + 6 - (x^2 - 5x + 6)}{(x - 2)(x + 3)} = \frac{x^2 + 5x + 4 - (x^2 - 5x + 4)}{(x - 4)(x + 1)},$$

$$\frac{10x}{x^2 + x - 6} = \frac{10x}{x^2 - 3x - 4},$$

$$x = 0 \ \text{ or } \ \frac{1}{x^2 + x - 6} = \frac{1}{x^2 - 3x - 4},$$

$$\imath e. \quad x^2 + x - 6 = x^2 - 3x - 4,$$
$$4x = 2,$$
$$x = \tfrac{1}{2},$$

$0, \tfrac{1}{2}$ are the reqd solutions

9   $x - \dfrac{1}{x} = \dfrac{4}{21}\left(x^3 - \dfrac{1}{x^3}\right)$ 10 $(x+1)(x+2)(x+3)(x+4) = 24 + 34(x^2 + 5x)$

11   $6x^3 + (5-x)^3 = 5(5+x)(5+2x)$ 12 $(x+1)(x+2)(x+3)(x+4) = 24$

13   $\dfrac{x-1}{x+1} + \dfrac{x-4}{x+4} = \dfrac{x-2}{x+2} + \dfrac{x-3}{x+3}$ 14 $x(x+1)(x+2)(x+3) = 120$

15   $x^2 + 3x - \dfrac{9}{2} + \dfrac{2}{x^2 + 3x} = 0$ 16 $16x(x+1)(x+2)(x+3) = 9$

17   $x^4 + 2x^3 - 11x^2 + 4x + 4 = 0$

CHAPTER XXVL

GRAPHIC SOLUTION OF QUADRATIC EQUATIONS

151. *Solve the equation $2x^2 - x - 10 = 0$ graphically*
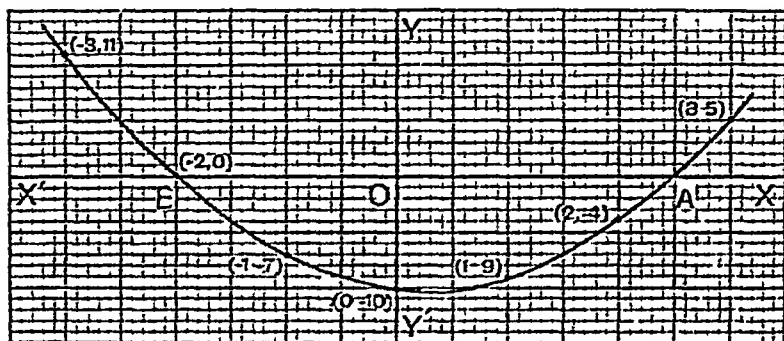

First Method. Let us trace the graph of $y = 2x^2 - x - 10$, using a unit for the x values 10 times as large as that for the y values, as in Art 134

When

$x = 0$	1	2	3		-1	-2	-3
$2x^2 = 0$	2	8	18		2	8	18
$-x - 10 = -10$	-11	-12	-13		-9	-8	-7
$y = 2x^2 - x - 10 = -10$	-9	-4	5		-7	0	11

$(0, -10)$, $(1, -9)$, $(2, -4)$, $(3, 5)$, $(-1, -7)$, $(-2, 0)$ $(-3, 11)$ are points on the graph

Marking these points as shown in the diagram, and drawing the curve carefully, we have the graph of $y = 2x^2 - x - 10$

At the points A and B where this curve meets XOX' the axis of x, $y = 0$,   at those points $2x^2 - x - 10 = 0$

But OA and OB are the values of x at these points,

they are the roots of the given equation

From the diagram we see that the roots are 2 5 and -2

Second Method   First trace the graph of $y = x^2$, using a unit for the x values 10 times as large as that for the y values, as in Art 134
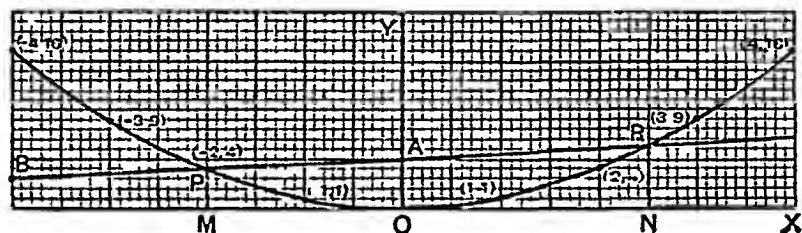

We thus obtain the curve POR as in the diagram

Then trace in the same diagram, and *with the same units*, the graph of $2y - x - 10 = 0$

We know this to be a straight line   (Art 71)

When $x = 0$, $y = 5$,   (0, 5) is a point on the straight line

Mark this point A

When $x = -4$, $y = 3$, $(-4, 3)$ is also on the line

Mark this point B, and join AB

The straight line AB is the graph of $2y - x - 10 = 0$

Mark the points P and R where this line meets the curve POR

Now at the point P, the ordinate PM is the same for both graphs, i e y is the same in both the equations $y = x^2$ and $2y - x - 10 = 0$,   at the point P, $2x^2 - x - 10 = 0$ OM is therefore a root of this equation   From the diagram OM $= -2$

In precisely the same way, the ordinate at R is the same in both equations, $y = x^2$ and $2y - x - 10 = 0$,   ON is another root of the equation $2x^2 - x - 10 = 0$ From the diagram ON $= 2$ 5,

the reqd roots are -2 and 2 5

152 *Find graphically, correct to one decimal place, the roots of the equation* $5x^2 + 10x - 29 = 0$

Trace the graph of $y = 5x^2 + 10x - 29$
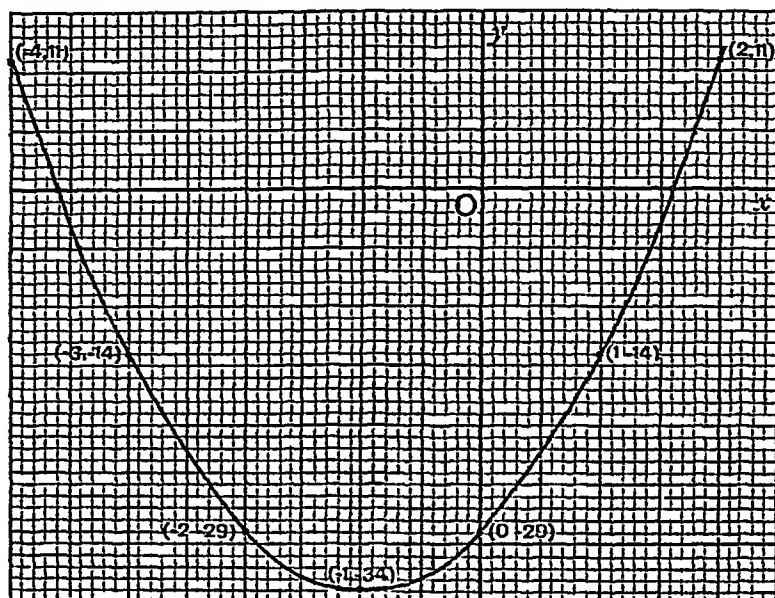

When

$x=0$	1	2	3
$5x^2=0$	5	20	45
$10x-29=-29$	-19	-9	1
$y=-29$	-14	11	46

When

$x=-1$	-2	-3	-4
$5x^2=5$	20	45	80
$10x-29=-39$	-49	-59	-69
$y=-34$	-29	-14	11

Plotting the points $(0, -29)$ $(1, -14)$ $(2, 11)$ $(-1, -34)$ $(-2, -29)$ $(-3, -14)$ $(-4, 11)$ and taking the x unit ten times as large as the y unit, we have the curve as shown in the diagram

The equation is satisfied when $5x^2 + 10x - 29 = 0$, i e when $y = 0$, i e where the curve cuts the axis of x

From the diagram, the roots required are
$$1\ 6,\quad -3\ 6$$

Verification.   When $x = 1\ 6$, $5x^2 + 10x - 29 = 5(2\ 56) + 16 - 29$
$$= 12\ 8 + 16 - 29$$
$$= -2$$

Thus when $x = 1\ 6$, $5x^2 + 10x - 29$ is nearly zero

1 6 is an approximate root   In the same way we can verify the fact that $-3\ 6$ is an approximate root

If we trace the graphs of $y = x^2$ and $y = x^2 + bx + c$, where b and c have any assigned values, using the same units in each case, we shall obtain the same curve in different positions   This is easily seen by cutting out one curve and superimposing it on the other

In general, it will be found that the graph of any equation in two variables, whose terms of the second degree form a perfect square, is a parabola

For instance, if we plotted a number of points on the curve $(2x + 3y)^2 + 3x - 2y + 5 = 0$ and joined them by an even curve we should obtain a parabola

MAXIMUM AND MINIMUM VALUES OF QUADRATIC EXPRESSIONS OF ONE VARIABLE

153 These all hinge upon the fact that a perfect square is always positive, i e it cannot be less than zero

To find the minimum value of $x^2 - 4x + 7$ for real values of x.
$$x^2 - 4x + 7 = (x - 2)^2 + 3$$
.   the given expression is least when $(x - 2)^2 = 0$
The reqd minimum value is therefore 3

To find the minimum value of $x^2 - 4x + 7$ graphically
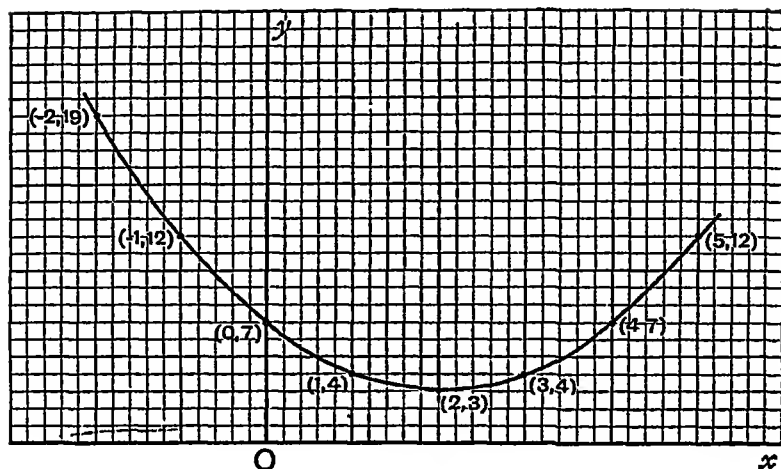

Let us trace the graph of $y = x^2 - 4x + 7$

When

$x = -2$	-1	0	1	2	3	4	5
$x^2 + 7 = 11$	8	7	8	11	16	23	32
$-4x = 8$	4	0	-4	-8	-12	-16	-20
$y = 19$	12	7	4	3	4	7	12

Plotting the pts $(-2, 19)$ $(-1, 12)$ $(0, 7)$ $(1, 4)$ $(2, 3)$ $(3, 4)$ $(4, 7)$ $(5, 12)$ and joining them by an even curve, we have the curve shown in the diagram

From it we see that the minimum value of y, i e of $x^2 - 4x + 7$, is 3

[In the diagram the x unit is taken five times as large as the y unit]

To find the maximum value of $3\,5 + 4x - 4x^2$ for real values of x.
$$3\,5 + 4x - 4x^2 = 4\,5 - (1 - 4x + 4x^2)$$
$$= 4\,5 - (1 - 2x)^2$$

the given expression is greatest when $(1-2x)^2$ is least, $i\,e$ when $1-2x=0$

Hence 4 5 is the maximum value reqd

By plotting the graph of $y=3\,5+4x-4x^2$, we can find the maximum value graphically, as in the preceding example

154 *Between what values of x is the expression $19x-2x^2-35$ positive?*

Let y denote the given expression

$$y=-(2x^2-19x+35)=-(2x-5)(x-7)$$
$$=(2x-5)(7-x)=2\left(x-\tfrac{5}{2}\right)(7-x)$$

When $x<2\tfrac{1}{2}$, $x-\tfrac{5}{2}$ is negative and $7-x$ is positive ,

y is negative

When $x>2\tfrac{1}{2}$ but <7, $x-\tfrac{5}{2}$ is positive and $7-x$ is positive ,

y is positive

When $x>7$, $x-\tfrac{5}{2}$ is positive and $7-x$ is negative ,

y is negative

the given expression is only positive as long as x is between $2\tfrac{1}{2}$ and 7

This may be seen graphically by plotting the curve

$$y=19x-2x^2-35$$

CHAPTER XXVII

SIMULTANEOUS QUADRATIC EQUATIONS

155 In this chapter we shall consider simultaneous equations, where one at least is of a higher degree than the first

The methods of solution are various, but the student should endeavour to reduce the equations to the forms

$$ax+by=c,$$
$$ax-by=c'$$

Addition and subtraction will then effect the solution

Example 1   Solve the equations $25x^2-y^2=84$, $5x-y=6$

By division, $5x+y=14$
Also $5x-y=6$
Adding, $10x=20$, $x=2$
Subtracting, $2y=8$, $y=4$
           $x=2$, $y=4$ is the reqd solution

Example 2   Solve the equations $3x+y=9$,   (1)
                                        $xy=6$ (2)

Squaring equation (1) $9x^2+6xy+y^2=81$
From (2) $12xy=72$
Subtracting, $9x^2-6xy+y^2=9$
Taking the sq root, $3x-y=\pm3$
We now have the two cases,

$$\left.\begin{array}{l}3x+y=9,\\3x-y=3\end{array}\right\}\qquad\qquad \begin{array}{l}3x+y=9,\\3x-y=-3\end{array}$$

Adding, $6x=12$, $6x=6$,
                     $x=2$ $x=1$
Subtracting, $2y=6$, $2y=12$,
                     $y=3$ $y=6$

$\left.\begin{array}{l}x=2\\y=3\end{array}\right\}$ and $\left.\begin{array}{l}x=1\\y=6\end{array}\right\}$ are the reqd solutions

Example 3   Solve the equations $9x^2 + y^2 = 52$,   (1)

$$xy = 8 \qquad (2)$$

From (2) $6xy = 48$ (3)

Adding to (1) *to complete the square*,

$$9x^2 + 6xy + y^2 = 100$$

Taking the sq root $3x + y = \pm 10$

Also, in the same way, subtracting (3) from (1),

$$9x^2 - 6xy + y^2 = 4$$
$$3x - y = \pm 2.$$

There are now four cases,

$$
\begin{array}{llll}
3x + y = 10, & 3x + y = 10, & 3x + y = -10, & 3x + y = -10 \\
3x - y = 2 & 3x - y = -2 & 3x - y = 2 & 3x - y = -2
\end{array}
$$

Adding, $6x = 12,$ $6x = 8,$ $6x = -8,$ $6x = -12,$

           $x = 2$ $x = \frac{4}{3}$ $x = -\frac{4}{3}$ $x = -2.$

Subtracting, $2y = 8,$ $2y = 12,$ $2y = -12,$ $2y = -8,$

           $y = 4$ $y = 6$ $y = -6$ $y = -4$

Hence the reqd solutions are

$$
\begin{array}{llll}
x = 2, & x = \frac{4}{3}, & x = -\frac{4}{3}, & x = -2, \\
y = 1 & y = 6 & y = -6 & y = -4
\end{array}
$$

Example 4   Solve the equations $4x^2 + y^2 = 17$,   (1)

$$2x + y = 5 \qquad (2)$$

From (2) by squaring, $4x^2 + 4xy + y^2 = 25$ (3)

     (1) by subtraction, $4xy = 8$

Subtracting this from (1) $4x^2 - 4xy + y^2 = 9$

Taking the sq root, $2x - y = \pm 3$

Hence $\begin{array}{l} 2x + y = 5, \\ 2x - y = 3 \end{array}$ or $\begin{array}{l} 2x + y = 5, \\ 2x - y = -3 \end{array}$

Adding, $4x = 8,$ $4x = 2$

              $x = 2$ $x = \frac{1}{2}$

Subtracting, $2y = 2,$ $2y = 8,$

             $y = 1$ $y = 4$

             $\begin{array}{l} x = 2, \\ y = 1 \end{array}$ $\left.\begin{array}{l} x = \frac{1}{2}, \\ y = 4 \end{array}\right\}$ are the reqd solutions

Examples   XXVII. a

Solve the equations

1. $4x^2 - y^2 = 35,$
   $2x + y = 7$

2. $x^2 - y^2 = 21,$
   $x + y = 3$

3. $y^2 - 9x^2 = 28,$
   $y - 3x = 2$

4. $x^2 - xy = 35,$
   $x - y = 5$

5. $4x^2 + xy = 51,$
   $4x + y = 17$

6. $9x - 3y = 3,$
   $9x^2 - y^2 = 5$

7. $5x - 2y = 12,$
   $25x^2 - 4y^2 = 96$

8. $4x^2 - 25y^2 = -81,$
   $4x - 10y = 54$

9. $9x^2 - 49y^2 = 29,$

156 In the following equations, the student's aim should be to reduce the equations to one of the forms exemplified earlier in this chapter

    Example   Solve the equations

$$x^3+y^3=91, \tag{1}$$
$$x^2-xy+y^2=13 \tag{2}$$

Dividing, $x+y=7 \tag{3}$

Squaring, $x^2+2xy+y^2=49$

   from (2), $xy=12 \tag{4}$

Now solve equations (3) and (4) as in Example 2, Art 155

Examples   XXVII b

8 $x^4 + x^2y^2 + y^4 = 1281$,   **9** $x^4 + x^2y^2 + y^4 = 481$,   **10** $x^4 + x^2y^2 + y^4 = 2613$,

16. $\dfrac{1}{x^3} + \dfrac{4}{y^3} = 5$,   **17** $15(x^2 + y^2) = 34xy$,   **18** $\dfrac{x}{y} + \dfrac{y}{x} = \dfrac{257}{16}$,

   $xy = 1$ $\dfrac{1}{x} - \dfrac{1}{y} = 2$ $4(x + y) = 17$

19 $\dfrac{x}{y} + \dfrac{y}{x} = \dfrac{17}{4}$,   **20** $\dfrac{4x}{y} + \dfrac{y}{x} = \dfrac{17}{2}$,   **21** $\dfrac{1}{x^3} + \dfrac{1}{y^3} = 35$,

25 $8x^3 + y^3 = 2$,   **26** $8x^3 + 27y^3 = 2$,

   $x^2 - 2xy + y^2 = 1$ $4x^2 - 6xy + 9y^2 = 1$.

157. Solve the equations $2x^2y^2 - 13xy + 18 = 0$, (1)

$$x + y = \frac{9}{2}$$ (2)

Treating (1) as a quadratic for xy,

$$(2xy - 9)(xy - 2) = 0,$$

$$xy = \frac{9}{2} \text{ or } 2$$

The complete solution is then obtained by first solving the equations

$$x + y = \frac{9}{2}, \quad xy = \frac{9}{2},$$

and then the equations $x + y = \frac{9}{2}, \quad xy = 2$, as in Example 2, Art 155

158 When the variable terms in the equations are *homogeneous*, ι e *of the same degree*, the following method may be used

Solve the equations $12x^2 - 4xy + 11y^2 = 64$, (1)

$$16x^2 - 9xy + 11y^2 = 78$$ (2)

Eliminate the constant terms, by multiplying across (multiply the left-hand side of each equation by the right-hand side of the other)

$$78(12x^2 - 4xy + 11y^2) = 64(16x^2 - 9xy + 11y^2),$$

$$39(12x^2 - 4xy + 11y^2) = 32(16x^2 - 9xy + 11y^2)$$

Multiplying out, and re arranging,

$$77y^2 + 132xy - 44x^2 = 0,$$

$$7y^2 + 12xy - 4x^2 = 0,$$

$$(7y - 2x)(y + 2x) = 0,$$

$$y = \frac{2x}{7} \text{ or } y = -2x$$

$\left(\text{If the factors cannot be seen, solve as a quadratic for } \dfrac{y}{x},\right)$

(1) When $y = \dfrac{2x}{7}$　Substituting this value of y in (1),

$$x^2\left(12 - \frac{8}{7} + \frac{44}{49}\right) = 64,$$

whence

$$x^2 = \frac{49 \times 64}{576} = \frac{49}{9},$$

$$x = \pm\frac{7}{3},$$

$$y = \frac{2x}{7} = \pm\frac{2}{3}$$

(2) When $y = -2x$　Substituting this value in (1),

$$x^2(12 + 8 + 44) = 64,$$

$$x^2 = 1,$$

$$x = \pm 1,$$

$$y = -2x = \mp 2,$$

the reqd solutions are

$$x = \pm\frac{7}{3},\ \pm 1,$$

$$y = \pm\frac{2}{3},\ \mp 2$$

159 When the above methods are inapplicable, substitution from one equation in the other may be employed

Solve the equations　$3x^2 + 4xy + 5y^2 = 31,$　　　(1)

$$x + 2y = 5 \qquad\qquad (2)$$

From (2) $x = 5 - 2y$

Substituting this value of x in (1),

$$3(5 - 2y)^2 + 4y(5 - 2y) + 5y^2 = 31,$$

whence

$$9y^2 - 40y + 44 = 0,$$

$$(9y - 22)(y - 2) = 0,$$

$$y = \tfrac{22}{9} \text{ or } 2,$$

$$x = 5 - 2y = 5 - \tfrac{44}{9} \text{ or } 5 - 4$$

$$= \tfrac{1}{9} \text{ or } 1$$

GRAPHS (CIRCLES)

160 The distance of the point (x, y) from the origin
$= \sqrt{(x^2 + y^2)}$

Using this, we may also determine the graph of $y = \sqrt{(25 - x^2)}$
as follows   The equation may be written, $x^2 + y^2 = 25$

$$\sqrt{(x^2 + y^2)} = 5$$

This shows us that the point (x, y) moves at a constant distance
of 5 units from the origin

The graph is therefore a circle, whose centre is at the origin and
whose radius $= 5$

161 In the accompanying diagram, let P be the pt (x_1, y_1) and Q the pt (x_2, y_2)

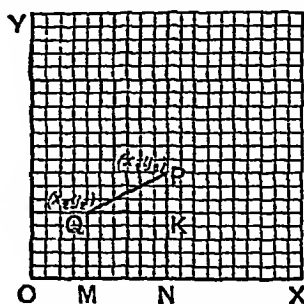

Draw PN and QM perp to the axis of x, and QK perp to PN

$$PK = y_1 - y_2, \text{ and } QK = x_1 - x_2$$

$$PQ = \sqrt{(QK^2 + PK^2)} = \sqrt{[(x_1 - x_2)^2 + (y_1 - y_2)^2]}$$

Thus we see that the distance between the two pts (x_1, y_1) and (x_2, y_2)

$$= \sqrt{(x_1 - x_2)^2 + (y_1 - y_2)^2}$$

162 *Trace the graph* of $x^2 + y^2 - 6x - 8y = 0$
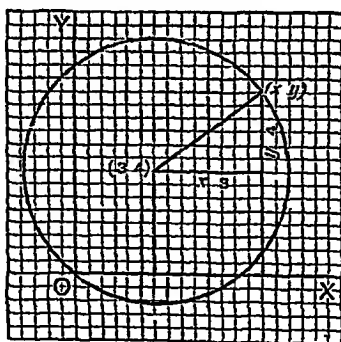

This equation may be written $(x - 3)^2 + (y - 4)^2 = 25$

$$\sqrt{(x - 3)^2 + (y - 4)^2} = 5$$

It is important to notice that if *no constant term* occurs in an equation, the corresponding graph passes through the origin, for by substitution we see that when $x = 0$, one value of y is 0

The graph of $x^2 + y^2 = 5$ is a circle whose radius is $\sqrt{5}$

A line $\sqrt{5}$ units long may be drawn either by using Pythagoras' Theorem $(2^2 + 1^2 = 5)$ or by the method of Art 136

GRAPHICAL SOLUTION OF SIMULTANEOUS QUADRATIC EQUATIONS

163. Simultaneous quadratics can often be readily solved by graphical methods

Example 1　Solve the following equations graphically

$$x - y = 5, \quad xy = 4$$
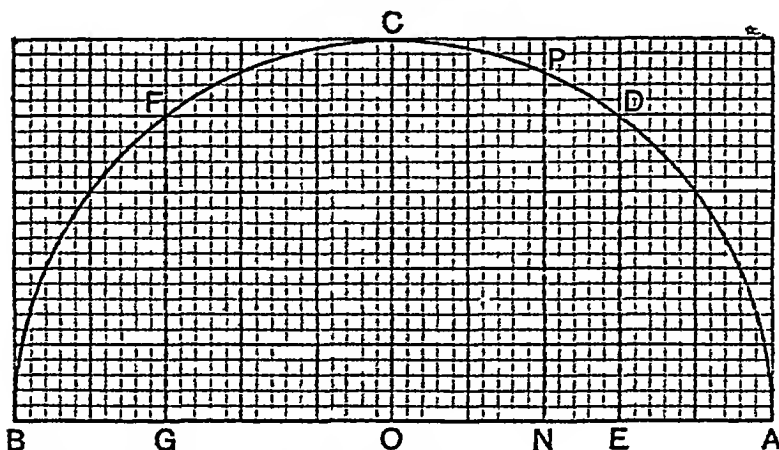

On AB, 5 in long (the diagram is reduced in printing), describe the semi-circle ACB

If P is any pt on the curve and PN is drawn perp to AB, we know, by Geometry, that　　　　$PN^2 = AN \cdot NB$

Mark the pts D, F on the curve where the lengths of the perpendiculars
DE, FG on AB are equal to 2 inches ($\sqrt{4}$)

Then $DE^2 = AE \cdot BE$, and $FG^2 = AG \cdot BG$

if AE$=x$ and BE$=y$,

$x + y = AB = 5$ and $xy = AE \cdot BE = DE^2 = 4$

AE, BE are solutions of the given equation

From the diagram $x=1$, $y=4$

In the same way, AG and BG are solutions, and we have

$x = 4$, $y = 1$

$\left. \begin{array}{l} x=1 \text{ or } 4, \\ y=4 \text{ or } 1, \end{array} \right\}$ is the complete solution

Example 2   Solve the following equations by the graphical method

$x - y = 3,\ xy = 4$
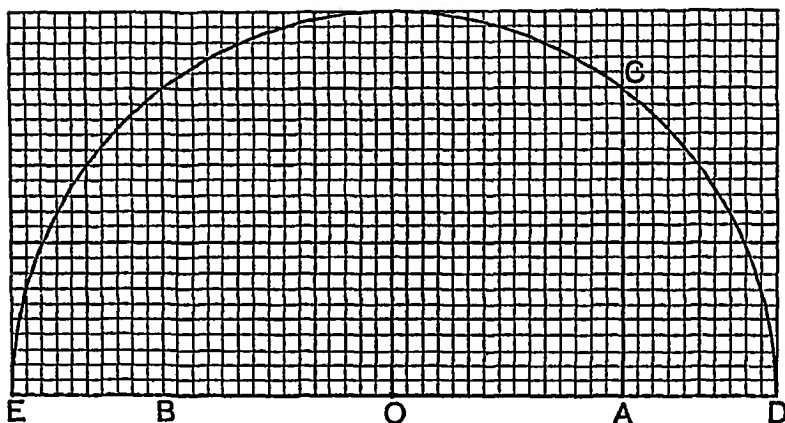

Take AB 3 in long and AC at rt ∠s to it 2 in ($=\sqrt{4}$) long   With O,
the mid pt of AB as centre, and OC radius, describe the semi-circle
ECD, meeting AB produced at D and E

As in the previous example, $CA^2 = DA \cdot AE$

if AE$=x$ and AD$=y$,

$x - y = AE - AD = AE - BE = AB = 3$

Also $xy = EA \cdot AD = AC^2 = 4$

AE and AD give a solution of the given equations

From the diagram see that $x=4$, $y=1$

N B $x=-1$, $y=-4$ is also a solution of these equations   The above
method does not give negative roots satisfactorily

The methods of the two preceding examples may be employed
to solve some quadratic equations

Thus to solve $x^2 - 7x + 9 = 0$, we have to factorize the expression
$x^2 - 7x + 9$, i e we have to find two numbers whose sum is 7 and
product 9

We can therefore use the method of Example 1

In the same way, to solve $x^2 - 3x - 36 = 0$, we have to find two numbers whose difference is 3 and product 36

We can therefore use the method of Example 2

164 *Solve the following equations graphically*
$$x^2 + y^2 - 4x - 2y + 1 = 0, \quad 2x - 3y = 3$$

The first equation may be written
$$(x - 2)^2 + (y - 1)^2 = 4$$

Hence its graph is a circle whose centre is at $(2, 1)$ and whose radius is 2

Draw the circle, and also draw, using the same axes and the same units, the graph of $2x - 3y = 3$, a str line through the pts $(1\ 5, 0)$, $(0, -1)$

The pts of intersection of the circle and str line give the roots required

165 *Find approximate solutions of the following equations by a graphical method* $x^2 + y^2 = 16, \quad xy = 6$
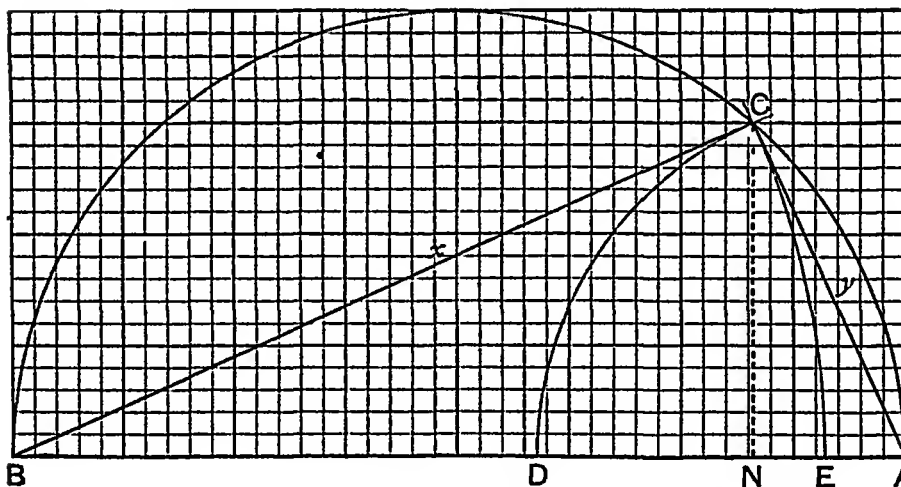

The following method depends upon the fact that if ABC is a triangle, right-angled at C, and CN is drawn perp to the hypotenuse AB, then AC BC = 2 △ ABC = CN AB   Now $\sqrt{16} = 4$, hence on AB, 4 in long, describe a semi-circle ACB, and take the

pt C such that the perp from C on $AB = \frac{6}{4} = 1\frac{1}{2}$ in   (Sqd paper should be used)

Then $AC^2 + BC^2 = AB^2 = 16$

Also $AC \cdot BC = CN \cdot AB = \frac{3}{2} \times 4 = 6$,

AC and BC are roots of the given equation

With centre A and radius AC describe a circle cutting AB at D

AC = AD = 1 65 approx from the diagram

In the same way BC = 3 65 approx,

1 65, 3 65 are roots of the given equation

166   *To trace the graph of $xy = 40$*

When

$x = \pm 2$	± 1	± 5	± 8	± 10	± 20	
$y = \pm 20$	± 10	± 8	± 5	± 4	± 2	

the upper signs being taken together, and the lower signs together
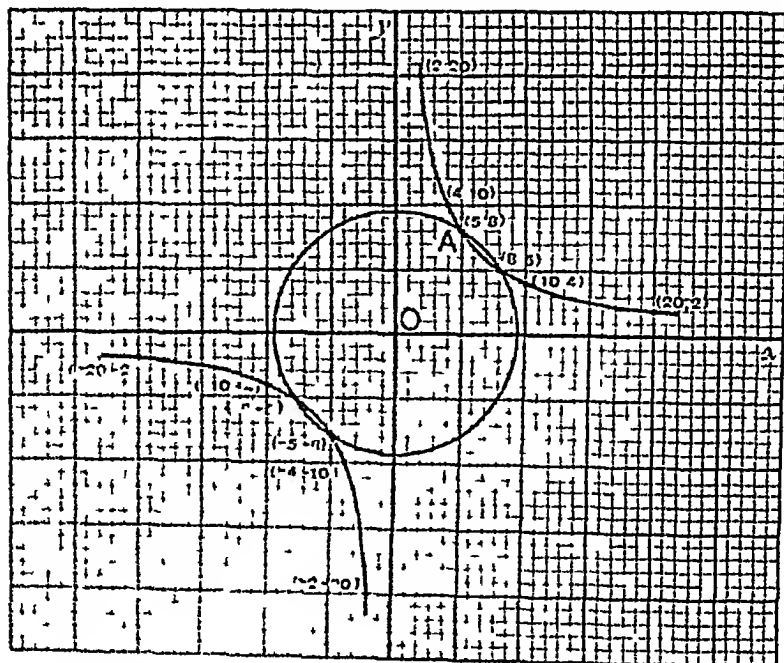

Plotting these pts and joining them by an even curve, we have the figure shown in the diagram

It is observed that the curve lies entirely in the first and third quadrants, and that the two branches are symmetrical in regard to both the axes of co-ordinates

Hence we have another method of solution of equations of the following type
$$x^2 + y^2 = 89,$$
$$xy = 40$$

We first draw the graph of $xy = 40$

The graph of $x^2 + y^2 = 89$ is a circle whose centre is at the origin, and radius $\sqrt{89}$ Since $89 = 25 + 64 = 5^2 + 8^2$, the length OA in the diagram is the radius   Describing the circle, and reading off the pts of intersection of the two curves, we have the following solutions

$$x = 8, \quad 5, \quad -5, \quad -8,$$
$$y = 5, \quad 8, \quad -8, \quad -5$$

167. *Find approximate roots of the equations*
$$xy = 80, \quad x - 2y = 10$$
From the following table of values, draw the graph of $xy = 80$

$x = \pm 4$	± 5	± 8	± 10	± 20	
$y = \pm 20$	± 16	± 10	± 8	± 4	

Draw the graph of $x - 2y = 10$, a str line through the pts $(10, 0)$, $(0, -5)$

The pts of intersection of the two graphs give the reqd roots They will be found to be

$$\left. \begin{array}{l} x = 18\ 6, \quad -8\ 6 \\ y = 4\ 3, \quad -9\ 3 \end{array} \right\} \text{approx}$$

Equations of the type of Examples 1 and 2 worked out in this chapter might also be solved by this method

CHAPTER XXIX

PROBLEMS INVOLVING QUADRATIC EQUATIONS

168 Example 1 A number of two digits is less than four times the product of its digits by 11, and the digit in the tens' place exceeds the digit in the units' place by four Find the number

Let x be the digit in the units' place

Then $x+4$ is the digit in the tens' place

The number $=10(x+4)+x=11x+40$

Four times the product of its digits $=4x(x+4)$,

$$4x(x+4)-(11x+40)=11,$$
$$4x^2+16x-11x-40=11,$$
$$4x^2+5x-51=0,$$
$$(x-3)(4x+17)=0,$$
$$x=3 \text{ or } -\frac{17}{4}$$

3 is the digit in the units' place, and $3+4\,(=7)$ the digit in the tens' place

<div align="center">73 is therefore the reqd number</div>

The solution $-\frac{17}{4}$ is inadmissible, because the digits of a number are *positive integers*

Example 2 A reduction of 2 pence a dozen in the price of eggs will give 6 more for three shillings and sixpence find the price per dozen

Let x pence be the price of 12 eggs

For 42 pence we obtain $\frac{12}{x}\times 42$ eggs

When $x-2$ pence is the price of 12 eggs, we obtain $\frac{12}{x-2}\times 42$ for 3s 6d

$$\frac{12}{x-2}\times 42-\frac{12}{x}\times 42=6,$$

$$\frac{84}{x-2} - \frac{84}{x} = 1,$$

$$84x - 84(x-2) = x^2 - 2x,$$

$$x^2 - 2x - 168 = 0,$$

$$(x-14)(x+12) = 0,$$

$$x = 14 \text{ or } -12$$

14 pence a dozen is the reqd price

Example 3   A train does a journey of 240 miles at a uniform rate , if it had travelled 4 miles an hour slower, it would have taken 2 hours more over the journey   find its rate of travelling   •

Let x miles an hour be the reqd rate of travelling

At the higher speed, the train took $\dfrac{240}{x}$ hours over the journey

At the slower speed, $x-4$ miles an hour, it took $\dfrac{240}{x-4}$ hrs over the journey

by hypothesis, $\dfrac{240}{x} = \dfrac{240}{x-4} - 2$

Multiplying up, $240(x-4) = 240x - 2x(x-4),$

$$2x^2 - 8x - 960 = 0,$$

$$x^2 - 4x - 480 = 0,$$

$$(x-24)(x+20) = 0 ,$$

$$x = 24 \text{ or } -20$$

the train travels at the rate of 24 miles an hour, the negative solution being inadmissible

It will be proved later on that every quadratic equation has two roots As a consequence of this, inadmissible solutions of problems involving quadratic equations will often occur   In this case the negative solution would imply that the train travelled *backwards* at 20 miles an hour

Example 4.   A man invests his money at compound interest for two years at a certain rate per cent and finds that he receives 5 shillings per cent more than if he had invested it at simple interest   Find the rate per cent

Let x be the rate per cent

At compound interest, 100£ amounts to $(100+x)$£ in the first year

The interest on $(100+x)$£ for the second year $= (100+x) \times \dfrac{x}{100}$

the interest on £100 for the two years $= x + \dfrac{(100+x)x}{100}$

At simple interest, the interest on 100£ for the two years $= 2x$

$$x + \frac{(100+x)x}{100} = 2x + \tfrac{1}{4},$$

whence $x^2 = 25,$

and $x = \pm 5$

5 per cent is the reqd rate of interest

Example 5   Two pipes running together will fill a cistern in $6\frac{2}{3}$ minutes If one pipe, running alone, took a minute less to fill the cistern, and the other pipe, running alone, took 2 minutes more to do the same, then the two, running together, would fill the cistern in 7 minutes   Find in what time the cistern will be filled by each pipe running alone

Let the first pipe, when running alone, fill the cistern in x minutes, and let the second pipe y .

When running alone, the first pipe fills $\frac{1}{x}$ of the cistern in one minute

$\qquad\qquad$ second $\qquad\quad \frac{1}{y}$

But since by hypothesis they running together fill the cistern in $\frac{20}{3}$ min in one minute $\qquad\qquad\qquad\qquad \frac{3}{20}$ of the cistern,

$$\frac{1}{x}+\frac{1}{y}=\frac{3}{20} \qquad (1)$$

In the second case, the first pipe fills the cistern in $x-1$ min
$\qquad\qquad$ second $\qquad\qquad\qquad y+2$

$$\frac{1}{x-1}+\frac{1}{y+2}=\frac{1}{7} \qquad (2)$$

From (1), $\qquad \frac{1}{x}=\frac{3}{20}-\frac{1}{y}=\frac{3y-20}{20y}$

$$x=\frac{20y}{3y-20} \qquad (3)$$

From (2), $\qquad \frac{1}{x-1}=\frac{1}{7}-\frac{1}{y+2}=\frac{y-5}{7(y+2)},$

$$x-1=\frac{7(y+2)}{y-5} \qquad (4)$$

From (3) and (4), $\qquad \frac{20y}{3y-20}-1=\frac{7(y+2)}{y-5}$

From this quadratic for y, $y=12$ will be found to be the only admissible solution

Substituting in (3), $\qquad\qquad x=15$

the pipes would fill the cistern in 15 and 12 minutes respectively

LITERAL EQUATIONS

169 Instead of numerical coefficients, we sometimes have to deal with coefficients denoted by symbols whose values are supposed to be known. Such coefficients are called literal.

The methods of solution are the same as in dealing with numerical coefficients.

Simple Equations   (One unknown)

Example 1   Solve the equation

$$\frac{x-a}{a-b}-\frac{x+a}{a+b}=\frac{2ax}{a^2-b^2}$$

Multiplying both sides by a^2-b^2,

$$(x-a)(a+b)-(x+a)(a-b)=2ax$$

Removing brackets, and transposing,

$$x(a+b-a+b-2a)=a^2-ab+a^2+ab,$$
$$2x(b-a)=2a^2$$

Dividing both sides by $2(b-a)$,

$$x=\frac{a^2}{b-a}$$

Examples   XXXI. a

Solve the equations

1. $\dfrac{x+a}{x-b}=1-\dfrac{x}{x-b}$

2. $\dfrac{a}{bx}-\dfrac{b}{ax}=a^2-b^2$

3. $\dfrac{a-b}{x-c}=\dfrac{a+b}{x+c}$

4. $\dfrac{x}{a-2b}=2+\dfrac{x}{2a-b}$

5. $\dfrac{acx}{b}+\dfrac{abx}{c}-\dfrac{1}{abc}=\dfrac{1}{abc}(1-b^2c^2x)$

6. $\dfrac{x+a}{x-c}+\dfrac{x+c}{x-a}=2$

7. $x-\dfrac{ax}{a+b}+a=\dfrac{a^2}{a-b}-\dfrac{b^2x}{a^2-b^2}$

8. $\dfrac{x}{a+c}=\dfrac{x+1}{a+b+c}$

9. $(x-a-b)^2=x^2-(a-b)^2$

10. $\dfrac{3x}{a}+2b(a-c)+\dfrac{x}{b}=c(a+b)+\dfrac{2x}{c}$

11. $\dfrac{1}{x-a}+\dfrac{1}{x-b}=\dfrac{2}{x}$

12. $\dfrac{q-r}{x-p}+\dfrac{r-p}{x}+\dfrac{p-q}{x-r}=0$

13. $\dfrac{x-2a}{x+2a}=\dfrac{x-a}{x+a}$

14. $\dfrac{x-b}{x-a}-\dfrac{x-a}{x-b}=\dfrac{2(a-b)}{x-(a+b)}$

15. $\dfrac{3\{ab-x(a+b)\}}{a+b}+\dfrac{(2a+b)b^2x}{a(a+b)^2}=\dfrac{bx}{a}-\dfrac{a^2b^2}{(a+b)^3}$

Solve the equations

16 $\dfrac{(a^2-1)(ax+1)}{a^2(x+a)}+\dfrac{(a^2+1)(x-a)}{ax+1}=\dfrac{ax+1}{x+a}+\dfrac{a(ax-1)}{ax+1}$

17 $\dfrac{x}{ax+b}+\dfrac{x}{a+bx}=\dfrac{a+b}{ab}$ 18 $\dfrac{a-a}{x-b}+\dfrac{x-c}{x-d}=2$ 19 $\dfrac{x+2a}{x-2b}=\left(\dfrac{x+a}{x-b}\right)^2$

20 $\dfrac{a}{x+a}+\dfrac{b}{x+b}=\dfrac{a+b}{x+a+b}$ 21 $\dfrac{x-2b}{a+b}+\dfrac{x-b}{a+2b}=\dfrac{2(x-a)}{3b}$

22 $(x+a)(x+b)+(x+b)(x+c)=(x+c)(x+d)+(x+d)(x+a)$

23 $\dfrac{1}{x-a}-\dfrac{1}{x-a+c}=\dfrac{1}{x-b-c}-\dfrac{1}{x-b}$

24 $\dfrac{1}{x-a}-\dfrac{1}{x-b}=\dfrac{a-b}{x^2-ab}$ 25 $\dfrac{ax}{x-b}+\dfrac{bx}{x-a}=a+b$

Simple Simultaneous Equations

170 **Example 1**   Solve the equations $ax+by=p$ (1)

$$bx-ay=q \quad ,$$ (2)

Multiplying (1) by a and (2) by b,

$$b^2x-aby=bq$$

Adding, $$x(a^2+b^2)=ap+bq,$$

$$x=\dfrac{ap+bq}{a^2+b^2}$$

Multiplying (1) by b and (2) by a,

$$abx+b^2y=bp,$$
$$abx-a^2y=aq$$

Subtracting, $$y(a^2+b^2)=bp-aq,$$

$$y=\dfrac{bp-aq}{a^2+b^2} ,$$

$$x=\dfrac{ap+bq}{a^2+b^2}, \quad y=\dfrac{bp-aq}{a^2+b^2} \text{ is the reqd solution}$$

Example 2   Solve the equations

$$\dfrac{x}{a}+\dfrac{y}{b}=1,$$ (1)

$$\dfrac{x}{b}+\dfrac{y}{a}=1$$ (2)

Subtracting, $$x\left(\dfrac{1}{a}-\dfrac{1}{b}\right)+y\left(\dfrac{1}{b}-\dfrac{1}{a}\right)=0,$$

$i\,e$ $$x\left(\dfrac{1}{a}-\dfrac{1}{b}\right)-y\left(\dfrac{1}{a}-\dfrac{1}{b}\right)=0 ,$$

$$x=y$$

$$x\left(\frac{1}{a}+\frac{1}{b}\right)=1,$$

$$x=\frac{ab}{a+b}=y$$

EQUATIONS IN AN IRRATIONAL FORM

172. The square root of any quantity may always be regarded as having two values equal in magnitude but of opposite signs For example, the square root of 49 is ± 7 When, however, such an expression as $\sqrt{2x+3}$ occurs in an equation it is usual to regard it as meaning the *positive* value of the square root of $2x+3$ It might be contended that $\sqrt{4x+7}-\sqrt{4x+3}=2$

was the same equation as $\sqrt{4x+7}+\sqrt{4x+3}=2$, but they are commonly regarded as being different, and instructions are given that after solving an equation of this sort, the answers obtained should be substituted in the original equation to see whether they satisfy it

Example 1   Solve the equation $\sqrt{4x+7}+\sqrt{4x+3}=6$

By transposition, $\sqrt{4x+3}=6-\sqrt{4x+7}$ (1)

Square, $4x+3=36-12\sqrt{4x+7}+4x+7$,   (2)

$$12\sqrt{4x+7}=36+7-3=40,$$

$$\sqrt{4x+7}=\tfrac{10}{3}$$

Square, $4x+7=\tfrac{100}{9}$,

$$4x=\tfrac{37}{9}, \qquad x=\tfrac{37}{36}$$

This root will be found on substitution to satisfy the equation

$$\sqrt{4x+7}+\sqrt{4x+3}=6$$

Example 2   Solve the equation $\sqrt{2x+3}+\sqrt{x-10}=6$ (1)

By transposing, $\sqrt{2x+3}=6-\sqrt{x-10}$

Squaring, $2x+3=36-12\sqrt{x-10}+x-10$,

$$x-23=-12\sqrt{x-10} \qquad (2)$$

Squaring, $x^2-46x+529=144(x-10)$

$$=144x-1440,$$

$$x^2-190x=-1969,$$

$$x=11 \text{ or } 179$$

The result 11 satisfies the equation, 179 does not   The fact is that in solving equation (1) we have introduced an additional root through squaring As we squared equation (2) it would have made no difference if we had written it $x-23=12\sqrt{x-10}$ Thus, in solving (1) we are also solving the equation $\sqrt{2x+3}-\sqrt{x-10}=6$, and this is the equation which is satisfied by the result 179 *

---

* This may be expressed in general terms

If we solve an equation $P=Q$ by squaring, we introduce generally an additional root

The equation becomes $P^2=Q^2$,

$$\text{i e } P^2-Q^2=0,$$

$$\text{i e } (P+Q)(P-Q)=0$$

Thus we have not only the original equation $P-Q=0$, but another one also, viz $P+Q=0$, i e $P=-Q$

Example 3 Solve $x^2 - x + 5\sqrt{2x^2 - 5x + 6} = \frac{1}{2}(3x + 33)$

$$2x^2 - 2x + 10\sqrt{2x^2 - 5x + 6} = 3x + 33,$$

$$2x^2 - 5x + 10\sqrt{2x^2 - 5x + 6} = 33$$

Let $\sqrt{2x^2 - 5x + 6} = y$, i e $2x^2 - 5x + 6 = y^2.$

Then the equation becomes

$$y^2 - 6 + 10y = 33,$$

$$y^2 + 10y - 39 = 0,$$

$$(y - 3)(y + 13) = 0,$$

i e $\sqrt{2x^2 - 5x + 6} = 3$ or -13;

$$2x^2 - 5x + 6 = 9,$$

$$2x^2 - 5x - 3 = 0$$

By substitution it will be seen that the negative value (-13) of y will not satisfy the equation

Thus the question has been reduced to the solution of a quadratic equation

The following plan is sometimes useful

Example 4 Solve $\sqrt{2x^2 + 9x - 1} + \sqrt{2x^2 - 7x + 7} = 6$ (1)

Now evidently $2x^2 + 9x - 1 - (2x^2 - 7x + 7) = 16x - 8,$ (2)

from (1) and (2) by division we obtain

$$\sqrt{2x^2 + 9x - 1} - \sqrt{2x^2 - 7x + 7} = \frac{8x - 4}{3},$$ (3)

by adding (1) and (3)

$$2\sqrt{2x^2 + 9x - 1} = \frac{8x - 4}{3} + 6 = \frac{8x + 14}{3},$$

$$6\sqrt{2x^2 + 9x - 1} = 8x + 14,$$

$$3\sqrt{2x^2 + 9x - 1} = 4x + 7,$$

by squaring, $18x^2 + 81x - 9 = 16x^2 + 56x + 49,$

$$2x^2 + 25x - 58 = 0,$$

$$(2x + 29)(x - 2) = 0,$$

$$x = 2 \text{ or } -\frac{29}{2}$$

Test, as before, to see whether the roots satisfy the equation

20 $\sqrt{5ax+4b}+\sqrt{5ax-4b}=4\sqrt{b}$

21 $\sqrt{x}+\sqrt{x-7}=\dfrac{21}{\sqrt{x-7}}$

22 $\sqrt{x+1}+\sqrt{x+4}=\sqrt{x+9}$

23 $\sqrt{x+2}+\sqrt{x}=\dfrac{4}{\sqrt{x+2}}$

24. $\sqrt{x+a\sqrt{4x+2a^2}}=a+\sqrt{x}$

25 $\sqrt{x-a^2}-\sqrt{x-b^2}=b-a$

26 $x^2+\sqrt{x^2+3x+5}=7-3x$

27 $x^2+\sqrt{x^2-5x+1}=5x+1$

28 $x^2+2x+6\sqrt{x^2+2x+5}=11$

29 $x^2+2x+4\sqrt{x^2+2x+8}=24$

30 $3x^2-2\sqrt{3x^2-2x+1}=2(x+1)$

31 $9x-3x^2+4\sqrt{x^2-3x+5}=11$

32 $2x^2-\sqrt{(x-3)(2x-7)}=13x+9$

33 $\sqrt{x^2+3x+6}-\sqrt{x^2+3x-1}=1$

173 We now give some miscellaneous equations, of which the following are types

Example 1 Solve the equations

$$x+y+z=19, \tag{1}$$
$$x^2+y^2+z^2=133, \tag{2}$$
$$yz=x^2 \tag{3}$$

Squaring (1), subtracting (2) from it, and dividing by 2,

$$xy+yz+zx=114, \tag{4}$$

from (3) $\qquad x(y+x+z)=114,$

and from (1) $\qquad x=6$

Substituting this value of x and solving for y and z we obtain the following solutions

$$x=6,\ 6,$$
$$y=9,\ 4,$$
$$z=4,\ 9$$

Example 2 Solve the equations

$$x(y+z)=7, \tag{1}$$
$$y(x+z)=4, \tag{2}$$
$$z(x+y)=5 \tag{3}$$

Adding (1), (2) and (3), and dividing by 2,

$$xy+yz+zx=8$$

Subtracting (1), (2) and (3) from this, in succession,

$$yz=1,$$
$$xz=4,$$
$$xy=3$$

Whence by multiplication, $\qquad x^2y^2z^2=12$

$$xyz=\pm\sqrt{12}$$

$$x=\pm2\sqrt{3},\ \ y=\dfrac{\pm\sqrt{12}}{4},\ \ z=\dfrac{\pm\sqrt{12}}{3}$$

Example 3 Solve the equations

$$x^2+2yz=48, \tag{1}$$
$$y^2+2zx=48, \tag{2}$$
$$z^2+2xy=48 \tag{3}$$

Adding and taking the square root of both sides,

$$x+y+z=\pm 12 \tag{4}$$

Subtracting (2) from (1) and factorizing,

$$(x-y)(x+y-2z)=0$$
$$x=y \text{ or } x+y=2z$$

(i) If $x=y$, from (1) $\qquad x^2+2xz=48,$

and from (3) $\qquad z^2+2x^2=48,$

whence $\qquad z=x$

$x=y=z$, and from (1) or (2) or (3)

$$x=\pm 4=y=z$$

(ii) If $\qquad\qquad x+y=2z,$

from (4) $\qquad z=\pm 4=x=y$ as before,

$x=y=z=\pm 4$ are the only solutions

Examples XXXI e

Solve the equations

1 $(x+y)^3+z^3=1125,$ 2 $\qquad xz=y^2,$ 3 $x^3-2x=\frac{7}{8}.$

$\qquad x+y+z=15,$ $\qquad\qquad x+y+z=13,$

$\qquad\qquad xy=24$ $\qquad\qquad x^2+y^2+z^2=91$

4. $\frac{x+y}{x-y}+10\frac{x-y}{x+y}=7,$ 5 $\quad xy+\frac{x}{y}=10,$ 6. $\quad x+y=a+b,$

$\qquad\qquad xy^3=3$ $\qquad\qquad xy^2-x=6y$ $\qquad\qquad \frac{a}{x}+\frac{b}{y}=2$

7 $x^2+xy+y^2=2x^2+3xy+y^2=c^2$

8 $\qquad x+y+z=7,$ 9 $\frac{x+a}{x+b}+\frac{x-a}{x-b}=\frac{a}{b}$

$\qquad xy+xz+yz=14,$

$\qquad\qquad xyz=8$

10 $\frac{(x-a)(x-b)}{(x-c)(x-d)}=\frac{x-a-b}{x-c-d}$ 11 $(ax+by)^2+(ay-bx)^2=2\left(\frac{a}{b}+\frac{b}{a}\right)^2,$

$\qquad\qquad\qquad\qquad\qquad\qquad \frac{x}{y}+\frac{y}{x}=2\frac{a^2+b^2}{a^2-b^2}$

12 $\quad x(y+z)=5,$ 13 $(x+y)(x+z)=1,$

$\quad y(x+z)=4,$ $\qquad\quad (y+z)(y+x)=4,$

$\quad z(x+y)=3$ $\qquad\quad (z+x)(z+y)=9$

14 Find the rational solutions of the equations,

$$\frac{x^2}{y^2}+\frac{y^2}{x^2}+\frac{x}{y}-\frac{y}{x}=\frac{106}{9}, \quad xy=3,$$

INDETERMINATE EQUATIONS

174. When we have but one equation involving *two* variables we can generally find any number of solutions   (Art 57)

Such equations, however, often admit of only a limited number of *positive integral* solutions

Example   *Find the positive integral solutions of the equation*

$$5x + 12y = 193 \tag{1}$$

By putting x or $y=0$, 1, 2 and so on, one pair of roots can generally be found without difficulty

Here we see *by trial* that one pair of roots is given by $x=5$, $y=14$

$$i e \quad 5 \times 5 + 12 \times 14 = 193 \tag{2}$$

Subtracting (2) from (1), $5(x-5) + 12(y-14) = 0$

$$5(x-5) = 12(14-y),$$

$$\frac{x-5}{14-y} = \frac{12}{5}$$

Now $\frac{12}{5}$ is in its lowest terms, and x and y must be positive integers,

$$x - 5 = 12p,$$

and $14 - y = 5p$, where p is an integer

$$i e \quad x = 5 + 12p, \quad\quad\quad \cdot \tag{3}$$

$$y = 14 - 5p \tag{4}$$

From (3) p cannot be <0, for then x would be negative

(4) >2 y

0, 1, 2 are the only admissible values of p

Hence from (3) and (4) the only positive integral solutions of the given equations are

$$(p=0) \quad \left.\begin{array}{l} x=5 \\ y=14 \end{array}\right\} \quad\quad (p=1) \quad \left.\begin{array}{l} x=17 \\ y=9 \end{array}\right\} \quad\quad (p=2) \quad \left.\begin{array}{l} x=29 \\ y=4 \end{array}\right\}$$

GRAPHICAL SOLUTION OF INDETERMINATE EQUATIONS

176   Example   Find the positive integral solutions of the equation

these are the reqd solutions

CHAPTER XXXII

THEORY OF QUADRATIC EQUATIONS

177 *To prove that a quadratic equation cannot have more than
two roots*

If possible, let the general quadratic equation
$$ax^2 + bx + c = 0$$
have *three different* roots a, β, γ

By hypothesis, each of these values of x satisfies the equation,
by substitution

$$aa^2 + ba + c = 0, \tag{1}$$
$$a\beta^2 + b\beta + c = 0, \tag{2}$$
$$a\gamma^2 + b\gamma + c = 0 \tag{3}$$

Subtracting (2) from (1), $a(a^2 - \beta^2) + b(a - \beta) = 0$
Dividing by $a - \beta$, which by hypothesis is not equal to zero,
$$a(a + \beta) + b = 0 \tag{4}$$

In the same way, subtracting (3) from (1) and dividing by $a - \gamma$,
$$a(a + \gamma) + b = 0 \tag{5}$$

Subtracting (5) from (4), $a(\beta - \gamma) = 0$,
$$a = 0 \text{ or } \beta - \gamma = 0,$$

which is impossible, for a is not equal to zero, nor is β equal to γ,
by hypothesis

the quadratic cannot have more than two roots

178 The square root of a negative quantity cannot be found
It is said to be '*imaginary*,' or '*unreal*,' or '*impossible*'

The quadratic equation $ax^2 + bx + c = 0$, will have

      (1) *real and different roots if $b^2 > 4ac$,*
      (2) *real and equal roots if $b^2 = 4ac$,*
      (3) *imaginary roots if $b^2 < 4ac$*

We have seen (Art 149), that the solution of this equation
may be thus written

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

(1) If $b^2 > 4ac$, $b^2 - 4ac$ is positive, and the value of $\sqrt{b^2 - 4ac}$
may be found,

    we then have two real and different roots,

$$\text{viz} \quad \frac{-b + \sqrt{b^2 - 4ac}}{2a} \text{ and } \frac{-b - \sqrt{b^2 - 4ac}}{2a}$$

(2) If $b^2 = 4ac$, $b^2 - 4ac = 0$,

$$x = -\frac{b}{2a} \text{ is the only solution },$$

in other words the roots are equal, and each equal to

$$-\frac{b}{2a}$$

(3) If $b^2 < 4ac$, $b^2 - 4ac$ is negative, and the value of

$$\sqrt{b^2 - 4ac} \text{ is imaginary}$$

Hence the equation in that case has no real roots

By means of the above we can determine the *nature* of the
roots of a quadratic, without actually effecting its solution

The student must be careful to distinguish between *irrational*
and *imaginary* roots

If the roots of $ax^2 + bx + c = 0$ are rational, $b^2 - 4ac$ must be a
perfect square

The roots of $x^2 - 2x - 2 = 0$ are $1 + \sqrt{3}$ and $1 - \sqrt{3}$
These are real but *irrational*
The roots of $x^2 - 2x + 4$ are $1 + \sqrt{-3}$, and $1 - \sqrt{-3}$
These are *imaginary*

179 *The roots of $ax^2 + bx + c = 0$ are equal, but of opposite sign if $b = 0$*

The roots are equal but of opposite sign,

if
$$\frac{-b + \sqrt{b^2 - 4ac}}{2a} = -\left[\frac{-b - \sqrt{b^2 - 4ac}}{2a}\right]$$

$$= \frac{b + \sqrt{b^2 - 4ac}}{2a},$$

i e if
$$\frac{2b}{2a} = 0,$$

i e if
$$b = 0$$

Example 1 When we solve the equation $x^2 + px - q^2 = 0$, the expression under the radical sign
$$= p^2 + 4q^2, \qquad (b^2 - 4ac)$$
which is positive

the roots of the equation are real and different for all values of p and q

Example 2 When we solve the equation $5x^2 - 2x + 4 = 0$, the quantity under the radical sign
$$= 4 - 4 \times 20, \text{ which is negative}$$
the equation has imaginary roots

If we drew the graph of $y = 5x^2 - 2x + 4$, as in Art 151, we should find that the curve does not meet the axis of x, *i e* no real value of x can be found which will make $5x^2 - 2x + 4$ vanish

Example 3 When we solve the equation $2x^2 - px + 8 = 0$, the expression under the radical sign
$$= p^2 - 4 \times 16 = p^2 - 64$$
$$\text{if } p^2 = 64, \text{ } i \text{ } e \text{ if } p = \pm 8,$$
the roots of $2x^2 - px + 8 = 0$ are equal

180 *In the quadratic equation $ax^2 + bx + c = 0$,*

(1) *the sum of the roots $= -\dfrac{b}{a}$,*

(2) *the product of the roots $= \dfrac{c}{a}$*

Let a and β be the roots
$$a = \frac{-b + \sqrt{b^2 - 4ac}}{2a},$$

$$\beta = \frac{-b - \sqrt{b^2 - 4ac}}{2a}$$

Adding, $\qquad a + \beta = -\dfrac{b}{a}$

Multiplying, $\qquad a\beta = \dfrac{b^2 - (b^2 - 4ac)}{4a^2}$ $\qquad [(p+q)(p-q) = p^2 - q^2]$

$$= \frac{4ac}{4a^2}$$

$$= \frac{c}{a}$$

If we write the equation in the form $x^2 + \dfrac{bx}{a} + \dfrac{c}{a} = 0$, we may express these results as follows

When the coefficient of x^2 in a quadratic equation is unity,

(1) the sum of the roots is equal to the coefficient of x with the sign changed ;

(2) the product of the roots is equal to the constant term

These results are of the greatest importance, and will be found most useful in solving problems concerned with the roots of quadratic equations

181 *If a and β are the roots of $ax^2 + bx + c = 0$,*

$$ax^2 + bx + c = a\,(x - a)(x - \beta)$$

$$ax^2 + bx + c = a\left(x^2 + \frac{bx}{a} + \frac{c}{a}\right)$$

$$= a\left[x^2 - (a + \beta)x + a\beta\right]$$

$$= a\,(x - a)(x - \beta)$$

In the same way, if a and β are the roots of $x^2 + px + q = 0$,

$$x^2 + px + q = (x - a)(x - \beta)$$

Example 1   The quadratic whose roots are -5 and 6 is

$$(x + 5)(x - 6) = 0,$$
$$\text{or} \qquad x^2 - x - 30 = 0$$

Example 2   If a and β are the roots of $x^2 - px + q = 0$, find the values of (1) $a - \beta$, (2) $a^2 + \beta^2$, (3) $a^3 + \beta^3$

(1) $\qquad\qquad\qquad\qquad a + \beta = p,$ $\qquad\qquad$ (1)
$$a\beta = q \qquad\qquad\qquad\qquad (2)$$

Squaring (1) and subtracting four times (2),

$$(a - \beta)^2 = p^2 - 4q ,$$
$$a - \beta = \pm\sqrt{p^2 - 4q}$$

(2) Squaring (1) and subtracting twice (2),
$$\alpha^2+\beta^2=p^2-2q$$

(3) Squaring (1) and subtracting three times (2),
$$\alpha^2-\alpha\beta+\beta^2=p^2-3q$$

Multiplying this with (1),
$$\alpha^3+\beta^3=p(p^2-3q)$$

Example 3   If α and β are the roots of $ax^2+bx+c=0$, form the equation whose roots are $\dfrac{1}{\alpha}$, and $\dfrac{1}{\beta}$

The sum of the roots of the reqd equation $=\dfrac{1}{\alpha}+\dfrac{1}{\beta}$

$$=\frac{\alpha+\beta}{\alpha\beta}=-\frac{b}{a}-\frac{c}{a}=-\frac{b}{c}$$

The product of the roots $=\dfrac{1}{\alpha\beta}=\dfrac{a}{c}$

the reqd equation is

$$x^2+\frac{bx}{c}+\frac{a}{c}=0,$$

or
$$cx^2+bx+a=0$$

182 *If a is positive and α, β are real roots of the equation $ax^2+bx+c=0$, the expression ax^2+bx+c vanishes when $x=\alpha$ or β, and is positive for all other values of x except for those lying between α and β*

(1) The values α and β satisfy the equation,
the expression ax^2+bx+c is zero when $x=\alpha$ or β

(2) $$\alpha+\beta=-\frac{b}{a}, \quad \alpha\beta=\frac{c}{a} \qquad \text{(Art 180)}$$

$$ax^2+bx+c=a\left(x^2+\frac{bx}{a}+\frac{c}{a}\right)$$
$$=a[x^2-(\alpha+\beta)x+\alpha\beta]$$
$$=a(x-\alpha)(x-\beta) \qquad (1)$$

Let α be greater than β

When $x>\alpha$, $x-\alpha$ is positive and $x-\beta$ is positive,
              from (1) ax^2+bx+c is positive

When $x<\alpha$ but $>\beta$, $x-\alpha$ is negative,
and $x-\beta$ is positive,
              from (1) ax^2+bx+c is negative.

Lastly, when $x<\beta$, $x-\alpha$ is negative,
and $x-\beta$ is negative,
              from (1) ax^2+bx+c is positive.

$$ax^2 + bx + c = 0, \text{ when } x = \alpha \text{ or } \beta,$$

is negative when x lies between α and β, -

and is positive for all other values of x

It follows that if a is negative and α and β are the roots of $ax^2 + bx + c = 0$, the expression $ax^2 + bx + c$ is zero when $x = \alpha$ or β, negative for all other values of x except for those lying between α and β

Example 1   To prove *graphically* that the expression $x^2 + x - 6$

   (i) vanishes when $x = 2$ or -3,

   (ii) is negative when x lies between 2 and -3,

   (iii) is positive for all other values of x

(i) If we draw the graph of $y = x^2 + x - 6$ as in Art 151, we shall see that the curve cuts the axis of x where $x = 2$ and $x = -3$

(ii) When x lies between these values, y is negative

(iii) For all other values y is positive

Example 2   Show that $\dfrac{x^2 - 3x + 4}{x^2 + 3x + 4}$ can never be greater than 7 nor less than $\frac{1}{7}$ for real values of x

Let $\dfrac{x^2 - 3x + 4}{x^2 + 3x + 4} = u$

Multiplying up and rearranging as a quadratic for x,

$$x^2(1 - u) - 3x(1 + u) + 4(1 - u) = 0$$

When we solve this quadratic for x, the expression under the radical sign

$$\begin{aligned}
&= 9(1 + u)^2 - 16(1 - u)^2 \qquad (b^2 - 4ac)\\
&= -7 + 50u - 7u^2\\
&= (-7 + u)(1 - 7u)\\
&= 7(u - 7)(\tfrac{1}{7} - u)
\end{aligned}$$

Hence if $u > 7$, $u - 7$ is positive, and $\frac{1}{7} - u$ is negative

   the expression under the radical sign is negative and x is imaginary

If $u < 7$ but $> \frac{1}{7}$, $u - 7$ is negative and $\frac{1}{7} - u$ is negative

   the expression under the radical sign is positive, and x is real

If $u < \frac{1}{7}$, $u - 7$ is negative and $\frac{1}{7} - u$ is positive

   the expression under the radical sign is negative and x is imaginary

Thus for real values of x, u cannot be greater than 7 or less than $\frac{1}{7}$
